# On permutation groups generated by time-varying Mealy automata 

By ADAM WORYNA (Gliwice)

#### Abstract

This paper is devoted to the groups generated by time-varying Mealy automata with a changing alphabet. It is proved that any finitely generated residually finite group can be realized as a group of some time-varying automaton with a finite set of states. Groups generated by various time-varying automata are considered.

## 1. Introduction

The theory of Mealy automata and groups generated by such automata have rapidly expanded in recent years. The groups of automata can be described as groups acting on the homogenous rooted tree. An extensive presentation of this theory is included in [3]. The idea of an automaton with a changing alphabet and a changing set of its internal states is a natural generalization. It allows to construct groups acting on level homogenous rooted trees which may be not homogeneous.

Let $A$ be a given time-varying automaton. Any state $q$ from the set $Q_{0}$ of its internal states defines a transformation $f_{q}$ on the set of words over the changing alphabet. The (semi)group $\left\langle f_{q}: q \in Q_{0}\right\rangle$ is called the (semi)group

[^0]generated by automaton $A$ or the automaton (semi)group defined by $A$. If the changing alphabet is finite any such (semi)group is residually finite.

The groups of automata are difficult to study for many simple automata. There is no standard to studying such groups. A changing alphabet brings specific difficulties. For instance the word problem is solvable in the class of groups generated by finite state automata with a fixed alphabet (see for example [9]) but there are finitely generated residually finite groups with undecidable word problem (for example [2], [6]). Hence the word problem is undecidable in the class of groups generated by finite state time-varying automata.

Section 2 contains definitions of a time-varying Mealy automaton and functions defined by such automaton as well as the description of groups generated by these functions in terms of wreath product. In Section 3 we show that any finitely generated residually finite group can be realized as a group of some time-varying automaton with a finite set of states. In Section 4 we study the wreath product $\mathbb{Z} \imath \mathbb{Z}_{n}$ as a group of some 2 -state automaton. Section 5 gives an example of a 2 -state automaton group in which every finite group can be embedded.

## 2. Groups defined by time-varying Mealy automata

The paper [10] includes the primary notions about time-varying Mealy automata, different types of such automata as well as a description of functions defined by these automata was given. Recall some useful definitions and facts.

A changing alphabet is an infinite sequence $X=\left(X_{t}\right)_{t \in \mathbb{N}_{0}}$ of nonempty finite sets $X_{t}$ (sets of letters). A word over a given changing alphabet $X$ is a finite sequence $x_{0} x_{1} \ldots x_{l}$, where $x_{i} \in X_{i}$ for $i=0,1, \ldots, l$. We denote by $X^{*}$ the set of all words over $X$ (including the empty word $\emptyset$ ).

Definition 1. A time-varying Mealy automaton over the changing alphabet $X$ is a quadruple

$$
A=(Q, X, \varphi, \psi)
$$

where:
(1) $Q=\left(Q_{t}\right)_{t \in \mathbb{N}_{0}}$ (sequence of sets of internal states),
(2) $\varphi=\left(\varphi_{t}\right)_{t \in \mathbb{N}_{0}}, \varphi_{t}: Q_{t} \times X_{t} \rightarrow Q_{t+1}$ (sequence of transition functions), (3) $\psi=\left(\psi_{t}\right)_{t \in \mathbb{N}_{0}}, \psi_{t}: Q_{t} \times X_{t} \rightarrow X_{t}$ (sequence of output functions).

An automaton $A$ with a fixed initial state $q \in Q_{0}$ is called the initial automaton and denoted by $A_{q}$. If $A$ is a given automaton then for every state $q \in Q_{0}$ the initial automaton $A_{q}$ defines a function $f_{q}: X^{*} \rightarrow X^{*}$ as follows:

$$
\begin{equation*}
f_{q}\left(x_{0} x_{1} \ldots x_{l}\right)=\psi_{0}\left(q_{0}, x_{0}\right) \psi_{1}\left(q_{1}, x_{1}\right) \ldots \psi_{l}\left(q_{l}, x_{l}\right) \tag{1}
\end{equation*}
$$

where $q_{0}=q$ and $q_{i}=\varphi_{i-1}\left(q_{i-1}, x_{i-1}\right)$ for $i=1, \ldots, l$. The function $f_{q}$ is called the automaton function defined by the initial automaton $A_{q}$.

An automaton $A$ is called permutational if the mapping of the set $X_{t}$ defined as follows

$$
x \mapsto \psi_{t}(q, x)
$$

is permutation for any $t \in \mathbb{N}_{0}$ and $q \in Q_{t}$. If $A$ is a permutational automaton then the functions $f_{q}$ are permutations on $X^{*}$ for all $q \in Q_{0}$.

Let $A_{q_{0}}=\left(Q, X, \varphi^{A}, \psi^{A}\right), B_{r_{0}}=\left(R, X, \varphi^{B}, \psi^{B}\right)$ be initial automata over a common alphabet $X$ and $f_{q_{0}}, h_{r_{0}}$ be automaton functions defined by the above automata. Then the superposition $h_{r_{0}} \circ f_{q_{0}}$ is an automaton function defined by the automaton $C_{s_{0}}=(S, X, \varphi, \psi)$ for which:

$$
\begin{aligned}
& S_{t}=Q_{t} \times R_{t}, s_{0}=\left(q_{0}, r_{0}\right), \\
& \varphi_{t}((q, r), x)=\left(\varphi_{t}^{A}(q, x), \varphi_{t}^{B}\left(r, \psi_{t}^{A}(q, x)\right)\right), \\
& \psi_{t}((q, r), x)=\psi_{t}^{B}\left(r, \psi_{t}^{A}(q, x)\right) .
\end{aligned}
$$

The automaton $C_{s_{0}}$ is called the product of the automata $A_{q_{0}}, B_{r_{0}}$. If $A_{q_{0}}$ is a permutational automaton then $f_{q_{0}}$ is a permutation. The inverse function $f_{q_{0}}^{-1}$ is also an automaton permutation defined by the automaton $D_{q_{0}}=(Q, X, \varphi, \psi)$ for which

$$
\varphi_{t}(q, x)=\varphi_{t}^{A}\left(q, x^{\prime}\right), \quad \psi_{t}(q, x)=x^{\prime}
$$

where the letter $x^{\prime}$ is defined by the equality $\psi_{t}^{A}\left(s, x^{\prime}\right)=x$. The automaton $D_{q_{0}}$ is called the inverse to the automaton $A_{q_{0}}$.

We consider the set $\mathrm{SA}(X)$ of all automaton functions defined by timevarying automata over a given changing alphabet $X$. Since the identity
function $\operatorname{id}_{X *}$ is an automaton transformation and the superposition of automaton functions is also of this type, the set $\mathrm{SA}(X)$ forms a monoid with $\mathrm{id}_{X *}$ as the neutral element. The construction of the product of automata and the inverse automaton allows to specify the following submonoids in SA $(X)$ (see [10]):
(1) automaton functions defined by automata with a constant sequence of its sets of states,
(2) automaton functions defined by automata with equi-bounded sets of states,
(3) the set $\mathrm{GA}(X)$ of automaton functions defined by permutational automata.

Let $A=(Q, X, \varphi, \psi)$ be a time-varying automaton. If there exist $T>0$ and $\tau \geq 0$ such that

$$
Q_{t+T}=Q_{t}, \quad X_{t+T}=X_{t}, \quad \varphi_{t+T}=\varphi_{t}, \quad \psi_{t+T}=\psi_{t}
$$

for every $t \geq \tau$ then $A$ is called a $(T, \tau)$-periodic automaton and the alphabet $X-\mathrm{a}(T, \tau)$-periodic alphabet.

Let $v \in X^{*}$ be a word of the length $n=|v|$ and $f$ be an automaton function defined by some initial automaton over $X$. Then we can define a function $f_{v}: X_{(n)} \rightarrow X_{(n)}$ by equality (see [10])

$$
f(v u)=f(v) f_{v}(u),
$$

where $X_{(n)}$ denotes the set of all finite sequences of letters in which the $i$-th letter belongs to $X_{n+i-1}$ for any $i=1,2, \ldots$. The function $f_{v}$ is called the $v$-remainder of $f$.

Let $X$ be a given changing alphabet. We consider the set $\operatorname{PSA}(X)$ of automaton functions defined by all periodic automata over $X$ as well as the set $\operatorname{FRSA}(X)$ of automaton functions with a finite set of remainders. The above sets are nonempty only if $X$ is periodic (see [10], Theorem 4.3).

Let $X$ be a $(T, \tau)$-periodic alphabet. If $f, h \in \operatorname{PSA}(X)$, where $f$ is defined by some $\left(T_{1}, \tau_{1}\right)$-periodic automaton and $h$ is defined by some $\left(T_{2}, \tau_{2}\right)$ periodic automaton then the product of these automata is a $\left(T^{\prime}, \tau^{\prime}\right)$-periodic automaton for $T^{\prime}=\operatorname{lcm}\left(T_{1}, T_{2}\right), \tau^{\prime}=\max \left(\tau_{1}, \tau_{2}\right)$. Of course the identity function $\operatorname{id}_{X^{*}} \in \operatorname{PSA}(X)$.

For the set $\operatorname{FRSA}(X)$ we have: $\operatorname{id}_{X^{*}} \in \operatorname{FRSA}(X)$ since all remainders of $\mathrm{id}_{X^{*}}$ are defined by words of length at most $T+\tau$. Moreover, for any $v$-remainder of $f \circ h$ we have $(f \circ h)_{v}=f_{h(v)} \circ h_{v}$. Hence, if $R_{f}$ and $R_{h}$ are sets of remainders then $\left|R_{f \circ h}\right| \leq\left|R_{f}\right| \cdot\left|R_{h}\right|$.

Thus, if $X$ is a periodic alphabet then $\operatorname{PSA}(X)$ and $\operatorname{FRSA}(X)$ form submonoids of $\mathrm{SA}(X)$. It is worth seeing that $\operatorname{FRSA}(X)$ is a proper submonoid of $\operatorname{PSA}(X)$ (see [10], Example 4.1).

The set $\mathrm{GA}(X)$ is the group of invertible elements of $\mathrm{SA}(X)$. The group $\mathrm{GA}(X)$ may be characterized as a certain wreath product.

Definition 2. The wreath product over an infinite sequence $\left(G_{0}, M_{0}\right)$, $\left(G_{0}, M_{0}\right), \ldots$ of permutation groups is the group of all permutations $g$ of the set $M=\prod_{i=0}^{\infty} M_{i}$, satisfying the following conditions
(i) if $g\left(x_{0}, x_{1}, \ldots\right)=y_{0}, y_{1}, \ldots$ then $y_{i}$ depends only on $i+1$ first coordinates $x_{0}, x_{1}, \ldots, x_{i}$ for any $i=0,1, \ldots$,
(ii) if we fix $x_{0}^{0}, \ldots, x_{i-1}^{0}$ then the transformation

$$
g_{x_{0}^{0}, \ldots, x_{i-1}^{0}}: x_{i} \mapsto y_{i}
$$

induced by $g$ is a permutation from the group $G_{i}$.
This wreath product we denote by

$$
\imath_{i=0}^{\infty}\left(G_{i}, M_{i}\right)=\imath_{i=0}^{\infty} G_{i} .
$$

Proposition 1. The set $\mathrm{GA}(X)$ of all automaton permutations defined by permutational time-varying automata over the changing alphabet $X$ forms (under superposition) a group isomorphic to the wreath product over the infinite sequence of symmetric groups on sets $X_{0}, X_{1}, X_{2}, \ldots$

$$
\operatorname{GA}(X) \cong \imath_{i=0}^{\infty} S\left(X_{i}\right) .
$$

Proof. For any $g \in \chi_{i=0}^{\infty} S\left(X_{i}\right)$ we consider a function $f_{g}: X^{*} \rightarrow X^{*}$ defined as:

$$
f_{g}\left(x_{0} x_{1} \ldots x_{l}\right)=g_{\emptyset}\left(x_{0}\right) g_{x_{0}}\left(x_{1}\right) g_{x_{0}, x_{1}}\left(x_{2}\right) \ldots g_{x_{0}, x_{1}, \ldots, x_{l-1}}\left(x_{l}\right)
$$

for an arbitrary word $x_{0} x_{1} \ldots x_{l}$, where $g_{x_{0}, \ldots, x_{i-1}} \in S\left(X_{i}\right)$ are transformations induced by $g$ according to the above definition of the wreath product. The map $g \mapsto f_{g}$ defines the required isomorphism.

## 3. Representation of groups by means of time-varying automata

For every permutational automaton $A$ we construct the group

$$
G(A)=\left\langle f_{q}: q \in Q_{0}\right\rangle
$$

The group $G(A)$ is called the group generated by automaton $A$. It is a residually finite group for every automaton $A$. It turns out that groups of this form include the class of finitely generated residually finite groups.

Theorem 1. For any n-generated residually finite group $G$ there is a time-varying automaton $A$ with an n-element set of states and such that

$$
G \cong G(A)
$$

Proof. Since $G$ is countable, its elements can be put in sequence

$$
g_{-1}=1, g_{0}, g_{1}, \ldots
$$

For the element $g_{i}(i \geq 0)$ there is a normal subgroup $N_{i} \triangleleft G$ of finite index such that $g_{i} \notin N_{i}$. The map

$$
g \mapsto\left(g N_{i}\right)_{i \in \mathbb{N}_{0}}
$$

defines the embedding of $G$ into the cartesian product $\prod_{i=0}^{\infty} G / N_{i}$. For any $i=0,1, \ldots$ since $\left|G / N_{i}\right|<\infty$, there is a finite set $X_{i}$ such that $G / N_{i}$ can be embedded into the symmetric group $S\left(X_{i}\right)$. Hence, the group $\prod_{i=0}^{\infty} G / N_{i}$ and consequently the group $G$ can be embedded into the cartesian product $\prod_{i=0}^{\infty} S\left(X_{i}\right)$ of symmetric groups. Let

$$
K=\left\langle\kappa_{0}, \kappa_{1}, \ldots, \kappa_{n-1}\right\rangle
$$

be the subgroup of $\prod_{i=0}^{\infty} S\left(X_{i}\right)$ isomorphic to $G$. We construct an atomaton $A=(Q, X, \varphi, \psi)$ in the following way:
(1) $X=\left(X_{t}\right)_{t \in \mathbb{N}_{0}}$,
(2) $Q_{t}=\left\{\kappa_{0}, \kappa_{1}, \ldots, \kappa_{n-1}\right\}$,
(3) $\varphi_{t}\left(\kappa_{i}, x\right)=\kappa_{i}, i=0,1, \ldots, n-1$,
(4) $\psi_{t}\left(\kappa_{i}, x\right)=\kappa_{i}^{(t)}(x), i=0,1, \ldots, n-1$,
where $\kappa_{i}^{(t)}$ is the permutation at the $(t+1)$-th position in $\kappa_{i}$. The automaton $A$ is permutational by definition.

Let $f_{\kappa_{i}}$ be the generator of $G(A)$ defined by the initial automaton $A_{\kappa_{i}}$. Then for any word $x_{0} x_{1} \ldots x_{l} \in X^{*}$ we have according to (1):

$$
\begin{aligned}
f_{\kappa_{i}}\left(x_{0} x_{1} \ldots x_{l}\right) & =\psi_{0}\left(\kappa_{i}, x_{0}\right) \psi_{1}\left(\kappa_{i}, x_{1}\right) \ldots \psi_{l}\left(\kappa_{i}, x_{l}\right) \\
& =\kappa_{i}^{(0)}\left(x_{0}\right) \kappa_{i}^{(1)}\left(x_{1}\right) \ldots \kappa_{i}^{(l)}\left(x_{l}\right) .
\end{aligned}
$$

For every $\kappa \in K$ we define a function $f_{\kappa}: X^{*} \rightarrow X^{*}$ as follows

$$
f_{\kappa}\left(x_{0} x_{1} \ldots x_{l}\right)=\kappa^{(0)}\left(x_{0}\right) \kappa^{(1)}\left(x_{1}\right) \ldots \kappa^{(l)}\left(x_{l}\right) .
$$

Then for any $\kappa, \kappa^{\prime} \in K$ the equality $f_{\kappa \circ \kappa^{\prime}}=f_{\kappa} \circ f_{\kappa^{\prime}}$ holds and $f_{\kappa} \in G(A)$ according to definition of $K$. Furthermore if $\kappa, \kappa^{\prime} \in K$ are different then $\kappa^{(t)}(x) \neq \kappa^{\prime(t)}(x)$ for some $t \in \mathbb{N}_{0}, x \in X_{t}$ and $f_{\kappa} \neq f_{\kappa^{\prime}}$. Hence the map $\kappa \mapsto f_{\kappa}$ defines the required isomorphism.

We denote by $+_{k}$ and $-_{k}$ the respective arithmetical operations $(\bmod k)$. Let $n>1$ be a given integer and $X=\left(X_{t}\right)_{t \in \mathbb{N}_{0}}$ be a changing alphabet of the form $X_{t}=\{0,1, \ldots, t+n-1\}$. If $u=z_{0} z_{1} \ldots z_{l}$ is any sequence of letters such that $z_{i} \in X_{i+\tau}$ for some $\tau \in \mathbb{N}_{0}, i=0,1, \ldots, l$ then for every integer $m$ we denote by $u \oplus m$ the following sequence of letters

$$
\left(z_{0}+_{\tau+n} m\right)\left(z_{1}+_{\tau+n+1} m\right) \ldots\left(z_{l}+_{\tau+n+l} m\right) .
$$

Example. Let $A=(Q, X, \psi, \varphi)$ be an automaton for which:
(1) $X_{t}=\{0,1, \ldots, t+1\}$,
(2) $Q_{0}=\left\{q_{0}, q_{1}\right\}, Q_{t}=\left\{q_{1}\right\}$ for $t \in \mathbb{N}$,
(3) $\varphi_{t}(q, x)=q_{1}$ for $t \in \mathbb{N}_{0}, q \in Q_{t}$,
(4) $\psi_{0}\left(q_{0}, x\right)=x$ for $x \in X_{0}$,
$\psi_{t}\left(q_{1}, x\right)=x+_{t+2} 1$.
The above automaton is presented in the picture ( 1 and $\pi_{i}$ constitute the neutral element and the cycle $(0,1, \ldots, i+1)$ of the symmetric group $S_{i+2}$ for any $i=0,1, \ldots)$.

We denote the generators $f_{q_{0}}$ and $f_{q_{1}}$ of $G(A)$ by $a$ and $b$ respectively. The generators transform a word $\epsilon u \in X^{*}$ with $\epsilon \in\{0,1\}$ in the following way $a(\epsilon u)=\epsilon(u \oplus 1), b(\epsilon u)=(\epsilon \oplus 1)(u \oplus 1)$ and both $a$ and $b$ have infinite order. Furthermore, $a b(\epsilon u)=(\epsilon \oplus 1)(u \oplus 2)=b a(\epsilon u)$. Let $c=a^{-1} b$. We easily check that $c^{2}$ is the identity function. Hence every element of $G(A)$ is of the form $c^{r} a^{s}, r \in\{0,1\}, s \in \mathbb{Z}$. We have $c^{r} a^{s}(\epsilon u)=(\epsilon \oplus r)(u \oplus s)$ and the mapping $c^{r} a^{s} \mapsto(r, s)$ defines an isomorphism $G(A) \cong \mathbb{Z}_{2} \times \mathbb{Z}$.

## 4. The wreath product $\mathbb{Z} \backslash \mathbb{Z}_{n}$ as a 2-state automaton group

Let $n>1$ be a given number and $A=(Q, X, \psi, \varphi)$ be an automaton in which:
(1) $X_{t}=\{0,1, \ldots, n+t-1\}$,
(2) $Q_{t}=\left\{q_{0}, q_{1}\right\}$,
(3) $\varphi_{0}\left(q_{0}, 0\right)=q_{1}, \varphi_{t}\left(q_{0}, x\right)=q_{0}$ for $x \neq 0$, $\varphi_{t}\left(q_{1}, x\right)=q_{1}$,
(4) $\psi_{t}\left(q_{0}, x\right)=x$, $\psi_{t}\left(q_{1}, x\right)=x+_{t+n} 1$.

We denote the generators $f_{q_{0}}, f_{q_{1}}$ of $G(A)$ by $\alpha$ and $\beta$ respectively. For a word $\epsilon u \in X^{*}$ with $\epsilon \in\{0,1, \ldots, n-1\}$ we have:

$$
\begin{aligned}
& \alpha(0 u)=0(u \oplus 1), \alpha(\epsilon u)=\epsilon u \quad \text { for } \epsilon=1, \ldots, n-1, \\
& \beta(\epsilon u)=(\epsilon \oplus 1)(u \oplus 1) .
\end{aligned}
$$

In particular both $\alpha$ and $\beta$ have infinite order.
Lemma 1. If an element $\gamma$ of $G(A)$ is represented by a word in $\alpha, \beta$ of the form

$$
\begin{equation*}
\alpha^{r_{1}} \beta^{s_{1}} \alpha^{r_{2}} \beta^{s_{2}} \ldots \alpha^{r_{k}} \beta^{s_{k}}, \tag{2}
\end{equation*}
$$

then we have

$$
\begin{equation*}
\gamma(\epsilon u)=(\epsilon \oplus s)(u \oplus(s+r(\epsilon))), \tag{3}
\end{equation*}
$$

where $s=\sum_{i=1}^{k} s_{i}, r(\epsilon)=\sum_{i} r_{i}$, where we sum over all $i$ for which $n \mid s_{i}+\cdots+s_{k}+\epsilon$ (if there are no suitable indexes, we assume $r(\epsilon)=0$ ).

Proof. By induction on the length of (2).
Thus the word (2) defines a unique ( $n+1$ )-tuple of integers

$$
\begin{equation*}
(s, r(0), r(1), \ldots, r(n-1)) . \tag{4}
\end{equation*}
$$

Using Lemma 1 we obtain the following algorithms solving the word and the conjugacy problem in $G(A)$ :

Let $w, w^{\prime}$ be words in $\alpha, \beta$. We calculate the $(n+1)$-tuples

$$
\begin{gathered}
(s, r(0), r(1), \ldots, r(n-1)) \\
\left(s^{\prime}, r^{\prime}(0), r^{\prime}(1), \ldots, r^{\prime}(n-1)\right)
\end{gathered}
$$

defined by $w$ and $w^{\prime}$ respectively. Then

$$
\begin{equation*}
w=w^{\prime} \Leftrightarrow n \mid s-s^{\prime} \quad \text { and } \quad s^{\prime}+r^{\prime}(i)=s+r(i) \tag{5}
\end{equation*}
$$

for $i=0,1, \ldots, n-1$. For the conjugacy problem we have $w, w^{\prime}$ are conjugate $\Leftrightarrow n \mid s-s^{\prime}$ and there is $\xi \in\{0,1, \ldots, n-1\}$ such that

$$
\sum_{i=0}^{\eta-1}\left(s^{\prime}+r^{\prime}\left(i s+_{n} j\right)\right)=\sum_{i=0}^{\eta-1}\left(s+r\left(i s+_{n} j+_{n} \xi\right)\right)
$$

for $j=0,1, \ldots, \operatorname{gcd}(n, s)-1$, where $\eta=\frac{n}{\operatorname{gcd}(n, s)}$.
The wreath product $\mathbb{Z} \imath \mathbb{Z}_{n}$ is a semi-direct product $\prod_{\mathbb{Z}_{n}} \mathbb{Z} \rtimes \mathbb{Z}_{n}$ with the action of $\mathbb{Z}_{n}$ on $\mathbb{Z}^{n}$ by a cyclic shift. In a sense this group is dual to the wreath product $\mathbb{Z}_{n} \backslash \mathbb{Z}$ which is known as the lamplighter group (see [4]). We mention some properties of the group $\mathbb{Z} \imath \mathbb{Z}_{n}$. The center of $\mathbb{Z} \imath \mathbb{Z}_{n}$ is isomorphic to $\mathbb{Z}$ and its quotient group is isomorphic to the semi-direct product $\mathbb{Z}^{n-1} \rtimes \mathbb{Z}_{n}$, where $\mathbb{Z}_{n}$ acts on $\mathbb{Z}^{n-1}$ by linear transformations as follows

$$
z \longmapsto\left(\begin{array}{cccccc}
0 & 0 & \ldots & 0 & 0 & -1 \\
1 & 0 & \ldots & 0 & 0 & -1 \\
0 & 1 & \ldots & 0 & 0 & -1 \\
\ldots & \ldots & \ldots & \ldots & \ldots & \ldots \\
0 & 0 & \ldots & 1 & 0 & -1 \\
0 & 0 & \ldots & 0 & 1 & -1
\end{array}\right)^{i} \cdot z, \quad z \in \mathbb{Z}^{n-1}
$$

for every $i \in \mathbb{Z}_{n}$. The wreath product $\left.\mathbb{Z}\right\rangle \mathbb{Z}_{n}$ is a metabelian, nonnilpotent group. The commutator subgroup $\left(\mathbb{Z} \imath \mathbb{Z}_{n}\right)^{\prime}$ is isomorphic to the cartesian product $\mathbb{Z}^{n-1}$. The abelianization of $\mathbb{Z} \imath \mathbb{Z}_{n}$ is isomorphic to $\mathbb{Z} \times \mathbb{Z}_{n}$.

Theorem 2. Let $G=G(A)$ be the group generated by the automaton A. Then
(i) $G \cong \mathbb{Z} 々 \mathbb{Z}_{n}$,
(ii) the stabilizer $S t_{G}(k) \cong \mathbb{Z}^{n}$ for any $k \geq 1$,
(iii) the quotient group $G / S t_{G}(1)$ is a cyclic group of order $n$ generated by $\beta S t_{G}(1)$. For $k>1$ the quotient group $G / S t_{G}(k)$ is isomorphic to the wreath product $\mathbb{Z}_{\tau}<\mathbb{Z}_{n}$, where $\tau=\operatorname{lcm}(n+1, \ldots, n+k-1)$,
(iv) for any $v \in X^{*}$ the vertex stabilizer $\operatorname{St}_{G}(v) \cong \mathbb{Z}^{n}$. For the orbit $\operatorname{Orb}_{G}(v)=\{\gamma(v): \gamma \in G\}$ we have

$$
\left|\operatorname{Orb}_{G}(v)\right|= \begin{cases}n & \text { if }|v|=1 \\ n \cdot \operatorname{lcm}(n+1, \ldots, n+|v|-1) & \text { if }|v|>1\end{cases}
$$

The group $G$ acts transitively on the set $X^{(l)}$ of words of length $l$ if and only if $l \leq 3$ in case $n$ is odd and $l \leq 4$ in case $n$ is even. Two words $\epsilon u, \epsilon^{\prime} u^{\prime} \in X^{*}$ belong to the same orbit if and only if $u^{\prime}=u \oplus r$ for some integer $r$.

Proof. (i) For an arbitrary $(n+1)$-tuple (4) there is a word in $\alpha, \beta$ which defines it. Indeed, an example of the required word is

$$
\begin{equation*}
w_{r_{0}, r_{1}, \ldots, r_{n-1}, s}=\alpha^{r_{0}-s} \beta \alpha^{r_{1}-s} \beta \ldots \alpha^{r_{n-2}-s} \beta \alpha^{r_{n-1}-s} \beta^{s-n+1} \tag{6}
\end{equation*}
$$

where $r_{i}=s+r\left(i-_{n} s\right)$. Hence any element of $G$ is represented by some word of the form (6). Furthermore, from the solution (5) any element of $G$ is represented by a unique such word with $r_{i} \in \mathbb{Z}(i=0,1, \ldots, n-1)$ and $s \in\{0,1, \ldots, n-1\}$. From Lemma 1 the multiplication formula for words (6) is described by the rules

$$
w_{r_{0}, r_{1}, \ldots, r_{n-1}, s} \cdot w_{r_{0}^{\prime}, r_{1}^{\prime}, \ldots, r_{n-1}^{\prime}, s^{\prime}}=w_{r_{0}^{\prime \prime}, r_{1}^{\prime \prime}, \ldots, r_{n-1}^{\prime \prime}, s^{\prime \prime}},
$$

where $s^{\prime \prime}=s+{ }_{n} s^{\prime}, r_{i}^{\prime \prime}=r_{i}+r_{i-s}^{\prime}$ for $i=0,1, \ldots, n-1$. Hence the map

$$
\begin{equation*}
w_{r_{0}, r_{1}, \ldots, r_{n-1}, s} \mapsto\left(\left(r_{0}, r_{1}, \ldots, r_{n-1}\right), s\right) \tag{7}
\end{equation*}
$$

is an isomorphism of $G$ and $\mathbb{Z} \imath \mathbb{Z}_{n}$.
(ii) If $\gamma$ is an element of $G$ defined by the word (6) then from Lemma 1 $\gamma \in S t_{G}(1) \Leftrightarrow s=0$. Similarly, for $k>1$

$$
\gamma \in S t_{G}(k) \Leftrightarrow s=0 \text { and } \tau \mid r(i) \quad \text { for } i=0,1, \ldots, n-1 .
$$

Now, the map $\phi: S t_{G}(k) \rightarrow \mathbb{Z}^{n}$ defined by the rule

$$
\phi\left(w_{r_{0}, r_{1}, \ldots, r_{n-1}, 0}\right)=\left(r_{0} / \tau^{\prime}, r_{1} / \tau^{\prime}, \ldots, r_{n-1} / \tau^{\prime}\right)
$$

is the required isomorphism, where $\tau^{\prime}= \begin{cases}1 & \text { if } k=1 \\ \tau & \text { if } k>1 .\end{cases}$
(iii) The map $\phi_{1}: G \rightarrow \mathbb{Z}_{n}$ defined by

$$
\phi_{1}\left(w_{r_{0}, r_{1}, \ldots, r_{n-1}, s}\right)=s
$$

is an epimorphism with $\operatorname{ker} \phi_{1}=S t_{G}(1)$. Similarly for $k>1$, the map $\phi_{k}: G \rightarrow \mathbb{Z}_{\tau} \imath \mathbb{Z}_{n}$ defined by

$$
\phi_{k}\left(w_{r_{0}, r_{1}, \ldots, r_{n-1}, s}\right)=\left(\left(\bar{r}_{0}, \bar{r}_{1}, \ldots, \bar{r}_{n-1}\right), s\right)
$$

is an epimorphism with $\operatorname{ker} \phi_{k}=S t_{G}(k)$, where $\bar{r}_{i}$ is the remainder of the division of $r_{i}$ by $\tau$.
(iv) It results from Lemma 1 and (iii).

Corollary. The growth function $\zeta_{G}(m)$ of $G$ is of order $m^{n}$.
Remark. A slight change of the alphabet $X$ in the above automaton gives a construction of the wreath product $\mathbb{Z} \imath \mathbb{Z}_{n}$ as a group acting spherically transitively.

## 5. The universal embedding by a 2-state automaton group

Let $A=(Q, X, \varphi, \psi)$ be an automaton in which:
(1) $X_{t}=\{0,1, \ldots, t+1\}$,
(2) $Q_{t}=\left\{q_{0}, q_{1}\right\}$,
(3) $\varphi_{t}\left(q_{0}, x\right)=q_{0}$,
$\varphi_{t}\left(q_{1}, x\right)=q_{1}$,
(4) $\psi_{t}\left(q_{0}, 0\right)=1, \psi_{t}\left(q_{0}, 1\right)=0, \psi_{t}\left(q_{0}, x\right)=x$ for $x \neq 0,1$, $\psi_{t}\left(q_{1}, x\right)=x+_{t+2} 1$.
The above automaton is presented in the picture $(\alpha$ is the cycle $(0,1)$ of the symmetric group $S_{i+2}$ for any $i=0,1, \ldots$ ).

Let $\alpha_{n}=(1,2), \beta_{n}=(1,2, \ldots, n+1)$ be cycles in the symmetric group $S_{n+1}$ for $n=1,2, \ldots$ and let $K=\langle\alpha, \beta\rangle$ be the group generated by two sequences of permutations

$$
\alpha=\left(\alpha_{1}, \alpha_{2}, \ldots\right), \quad \beta=\left(\beta_{1}, \beta_{2}, \ldots\right)
$$

of the infinite Cartesian product $\prod_{i=2}^{\infty} S_{i}$.
Theorem 3. Let $G=G(A)$ be the group generated by the automaton A. Then
(i) $G \cong K$,
(ii) every finite group can be embedded into $G$,
(iii) the action of $G$ on $X^{*}$ is spherically transitive,
(iv) the group $G$ contains no free subgroups of rank $>1$. The semigroup generated by $f_{q_{0}}, f_{q_{1}}$ is free,
(v) the commutator subgroup $G^{\prime}$ is a locally finite group and the abelianization $G / G^{\prime}$ is isomorphic to $\mathbb{Z}_{2} \times \mathbb{Z}$.

Proof. (i) For any word $x_{0} x_{1} \ldots x_{l} \in X^{*}$ if

$$
\begin{aligned}
f_{q_{0}}\left(x_{0} x_{1} \ldots x_{l}\right) & =y_{0} y_{1} \ldots y_{l} \\
f_{q_{1}}\left(x_{0} x_{1} \ldots x_{l}\right) & =z_{0} z_{1} \ldots z_{l}
\end{aligned}
$$

then

$$
\begin{equation*}
y_{i}=\alpha_{i+1}\left(x_{i}+1\right)-1, \quad z_{i}=\beta_{i+1}\left(x_{i}+1\right)-1 \tag{8}
\end{equation*}
$$

for $i=0,1, \ldots, l$. Hence, the image of $x_{i}$ depends on $x_{i}$ only. As in the proof of Theorem 1 the map $\alpha \mapsto f_{q_{0}}, \beta \mapsto f_{q_{1}}$ induces the required isomorphism.
(ii) It is enough to prove that the direct product $\coprod_{i=2}^{\infty} A_{i}$ of alternating groups is a subgroup of $K$. To this end we show that $N_{i} \triangleleft K$ for $i=$ $0,1, \ldots$, where

$$
N_{i}=\underbrace{\{1\} \times\{1\} \times \ldots\{1\}}_{i} \times A_{i+2} \times\{1\} \times\{1\} \times \ldots
$$

The case $i=0$ is obvious. Next, $N_{1}=\langle\gamma\rangle \triangleleft K$, where

$$
\gamma=\left(\alpha \beta^{2} \alpha \beta^{-2}\right)^{2}=(1,(1,2,3), 1,1, \ldots) \in K .
$$

For a given $n>1$ suppose that $N_{i} \triangleleft K$ for all $i<n$. For the element

$$
\delta=\left(\alpha \beta^{n+1} \alpha \beta^{-n-1}\right)^{2}
$$

we have $\delta=\left(\delta_{1}, \delta_{2}, \ldots, \delta_{n},(1,2, n+2), 1,1, \ldots\right)$, where all $\delta_{i}$ are even. It follows from the above assumption that elements $\kappa_{i}=(\underbrace{1, \ldots, 1}_{i-1}, \delta_{i}^{-1}, 1,1, \ldots)$
for $i=1, \ldots, n$ and consequently the product

$$
\kappa=\delta \cdot \kappa_{1} \cdots \cdots \kappa_{n}=(\underbrace{1, \ldots, 1}_{n},(1,2, n+2), 1,1, \ldots)
$$

belong to $K$. Hence $N_{n}=\left\langle\kappa^{K}\right\rangle \triangleleft K$.
(iii) Since the isomorphism $K \cong G$ is induced by the mapping $\alpha \mapsto f_{q_{0}}$, $\beta \mapsto f_{q_{1}}$, the spherical transitiveness results from (8) as well as from the inclusion $\coprod_{i=2}^{\infty} A_{i}<K$.
(iv) It is enough to show that $K$ does not contain a free group $F_{2}$. Since $\alpha$ has order 2 , any element of $K$ is defined by some word in $\alpha, \beta$ of the form

$$
\begin{equation*}
\alpha^{\epsilon} \beta^{s_{1}} \alpha \beta^{s_{2}} \ldots \alpha \beta^{s_{k}}, \quad \epsilon \in\{0,1\} . \tag{9}
\end{equation*}
$$

Let $s=\sum_{i=1}^{k} s_{i}$ be the sum of all exponents of $\beta$. First we prove the following

Lemma 2. The element $\gamma$ from $K$ represented by (9) has finite order if and only if $s=0$.

Proof of Lemma. Let $m=\sum_{i=1}^{k}\left|s_{i}\right|$. For any $n$, if $s=0$ and

$$
m+2<i<n-m-2
$$

the permutation of $\gamma$ at the $n$-th position maps $i$ into $\beta_{n}^{s}(i)=i$. Hence $\gamma$ has order less or equal to $\exp \left(S_{2 m+4}\right)$. From the other hand for any $j$, if

$$
j m+2<i<n-j m-2,
$$

then the $j$-th power of permutation at the $n$-th position in $\gamma$ maps $i$ in $\beta_{n}^{j s}(i)$. If $s \neq 0$ and $n>2 j m+5$ then $\beta_{n}^{j s}(i) \neq i$. Thus the $j$-th power of $\gamma$ is not the neutral element.

Now, let $\gamma, \gamma^{\prime} \in K$ and $s, s^{\prime}$ be sums of exponents of $\beta$ in some words in $\alpha, \beta$ representing $\gamma$ and $\gamma^{\prime}$ respectively. From Lemma 2, if $s=0$ or $s^{\prime}=0$ then $\gamma$ or $\gamma^{\prime}$ has finite order. Similarly, if $s, s^{\prime} \neq 0$, the element $\gamma^{s^{\prime}} \gamma^{\prime-s}$ has finite order. Hence, the group generated by $\gamma, \gamma^{\prime}$ is not isomorphic to $F_{2}$.

Let $\gamma$ and $\gamma^{\prime}$ be represented by two different words in $\alpha, \beta$ with nonnegative exponents and with the above defined sums $s, s^{\prime}$. We may assume that the word representing $\gamma$ ends with $\alpha$, while the word representing $\gamma^{\prime}$
ends with $\beta$. If $s \neq s^{\prime}$ then $\gamma \neq \gamma^{\prime}$, since $\gamma \gamma^{\prime-1}$ has infinite order by Lemma 2. If $s^{\prime}=s$ then for a suitably large $n$, the permutations of $\gamma$ and $\gamma^{\prime}$ at the $n$-th position map the number 2 to $l$ and $s+2$ respectively, where $l \leq s+1$. Thus $\gamma \neq \gamma^{\prime}$.
(v) Let $K_{\alpha}=\left\langle\alpha^{K}\right\rangle$ and $K_{\beta}=\left\langle\beta^{K}\right\rangle$ be groups generated by conjugacy classes of generators of $K$. The group $K_{\alpha}$ consists of all words (9) with $s=0$ well, torsion elements of $K$. Indeed, any such word can be expressed as

$$
\alpha^{\epsilon} \beta^{s_{1}} \alpha \beta^{-s_{1}} \cdot \beta^{s_{1}+s_{2}} \alpha \beta^{-s_{1}-s_{2}} \cdots \cdots \beta^{s_{1}+\cdots+s_{k-1}} \alpha \beta^{-s_{1}-\cdots-s_{k-1}} .
$$

Since $\alpha \beta K_{\alpha}=\beta K_{\alpha}$, the quotient group $K / K_{\alpha}$ is represented by $\beta^{i}, i \in \mathbb{Z}$. Thus the isomorphism $K / K_{\alpha} \cong \mathbb{Z}$ holds.

If $\gamma \in K_{\beta}$ then there is a word in $\alpha, \beta$ representing $\gamma$ in which $\alpha$ occurs an even number of times. We show as above that any such word represents an element from $K_{\beta}$. All permutations of $\gamma$ at even positions are even. Consequently $\alpha \notin K_{\beta}$ and $K_{\beta}$ consist exactly of those words in which $\alpha$ occurs an even number of times. Hence $K / K_{\beta} \cong \mathbb{Z}_{2}$.

From the isomorphisms $K / K_{\alpha} \cong \mathbb{Z}, K / K_{\beta} \cong \mathbb{Z}_{2}$ we obtain the inclusion $K^{\prime} \subseteq K_{\alpha} \cap K_{\beta}$. On the other hand, if $\gamma \in K_{\alpha} \cap K_{\beta}$ then $\gamma K^{\prime}=K^{\prime}$. Thus $K^{\prime}=K_{\alpha} \cap K_{\beta}$. In other words, $K^{\prime}$ consists of all torsion elements of $K$ such that permutations at all its positions are even. In particular $\coprod_{i=2}^{\infty} A_{i} \triangleleft K^{\prime}$. From above, $K / K^{\prime}$ is represented by $\alpha^{\epsilon} \beta^{i}, \epsilon \in\{0,1\}, i \in \mathbb{Z}$ and $G / G^{\prime} \cong K / K^{\prime} \cong \mathbb{Z}_{2} \times \mathbb{Z}$.

The group $K_{\alpha}$ is locally finite. Indeed, let $F=\left\langle\gamma_{1}, \ldots, \gamma_{n}\right\rangle$ be a finitely generated subgroup of $K_{\alpha}$. The element

$$
\gamma_{i}=\left(\gamma_{1}^{(i)}, \gamma_{2}^{(i)}, \ldots\right)
$$

is a Cartesian product of a finite number $r_{i}$ of infinite sequences of transpositions. Any permutation $\gamma_{j}^{(i)}$ of the above sequence changes at most $2 r_{i}$ elements. Thus, if $r=2 \sum_{i=1}^{n} r_{i}$ then there are sets $Z_{1}, Z_{2}, \ldots$ with at most $r$ elements each and such that for any $\gamma$ from $F$, the permutation at the $i$-th position changes only elements from $Z_{i}$. Hence, $F$ is isomorphic to some subgroup of the infinite Cartesian product of the symmetric groups $S_{r}$. Since the last group is locally finite, the group $F$ must be finite.

Now, using the sequence

$$
\coprod_{i=2}^{\infty} A_{i} \triangleleft K^{\prime} \triangleleft K_{\alpha}
$$

we obtain locally finiteness of $K^{\prime} \cong G^{\prime}$.
