Minus partial order in Rickart rings

By DRAGAN S. DJORDJEVIĆ (Niš), DRAGAN S. RAKIĆ (Niš) and JANKO MAROVČ (Maribor)

Abstract. The minus partial order is already known for complex matrices and bounded linear operators on Hilbert spaces. The notion is extended to Rickart rings and it is proved that this relation is a partial order. Some well-known results are generalized.

1. Introduction and motivation

Let $A$ be a ring with the unit 1. If $M \subseteq A$, then the right annihilator of $M$ is denoted by $M^\circ = \{x \in A : (\forall m \in M) mx = 0\}$, and the left annihilator of $M$ is denoted by $M^\circ = \{x \in A : (\forall m \in M) mx = 0\}$. $M^\circ$ is the right ideal of $A$, and $\circ M$ is a left ideal of $A$. Particularly, if $a \in A$ and $M = \{a\}$, then we shortly use $a^\circ = \{a\}^\circ$ and $\circ a = \circ \{a\}$.

The set of idempotents of $A$ is denoted by $A^\bullet = \{p \in A : p^2 = p\}$.

A ring $A$ is a Rickart ring, if for every $a \in A$ there exist some $p, q \in A^\bullet$ such that $a^\circ = pA$ and $\circ a = Aq$. Note that if $A$ is a Rickart ring, then $A$ has a unity element. The proof is similar to that used for Rickart $*$-rings [1].

Let $H$ be a Hilbert space, $\mathcal{L}(H)$ the set of all bounded linear operators on $H$, and let $\mathcal{R}(A)$ and $\mathcal{N}(A)$ denote the range and the null-space of $A \in \mathcal{L}(H)$. If

for a finite dimensional Hilbert space \( H \) Hartwig [3] defined a partial order in \( \mathcal{L}(H) \) in the following way:

\[
A \preceq B \quad \text{if and only if} \quad \rank(B - A) = \rank(B) - \rank(A).
\]

He also observed that there exists another equivalent definition of this order, namely

\[
A \preceq B \quad \text{if and only if} \quad A^- A = A^- B \quad \text{and} \quad AA^- = BA^-,
\]

where \( A^- \) is a generalized inner inverse of \( A \), i.e. \( AA^- A = A \). The partial order \( \preceq \) is thus usually called the minus partial order.

In [6] Šemrl extended the minus partial order in \( \mathcal{L}(H) \) for an arbitrary Hilbert space \( H \). The notion of a rank of an operator (equivalently, a rank of a finite complex matrix) can not be applied for bounded linear operators on general Hilbert spaces. Moreover, \( A \in \mathcal{L}(H) \) has a generalized inner inverse if and only if its image is closed. Since Šemrl could not use the notion of rank of an operator and since he did not want to restrict his attention only to closed range operators, he found a new approach how to extend the minus partial order. He introduced another equivalent definition of the minus partial order: for \( A, B \in \mathcal{L}(H) \), where \( H \) is a finite dimensional Hilbert space, we have \( A \preceq B \) if and only if there exist idempotent operators \( P, Q \in \mathcal{L}(H) \) such that \( \mathcal{R}(P) = \mathcal{R}(A), \mathcal{N}(Q) = \mathcal{N}(A), \mathcal{R}(P) = \mathcal{R}(B) \quad \text{and} \quad \mathcal{N}(Q) = \mathcal{N}(B) \).

Recall that the range of an idempotent operator \( P \in \mathcal{L}(H) \), where \( H \) can be a general Hilbert space, is closed. Using the same equations, only adding the closure on \( \mathcal{R}(A) \) Šemrl extended the concept of the minus partial order in \( \mathcal{L}(H) \) for an arbitrary Hilbert space \( H \):

**Definition 1.1.** Let \( H \) be a Hilbert space and let \( A, B \in \mathcal{L}(H) \). Then \( A \preceq B \) if and only if there exists idempotents \( P, Q \in (\mathcal{L}(H))^* \) such that the following hold:

1. \( \mathcal{R}(P) = \mathcal{R}(A) \);
2. \( \mathcal{N}(A) = \mathcal{N}(Q) \);
3. \( PA = PB \);
4. \( AQ = BQ \).

Šemrl proved that \( \preceq \) is indeed a partial order in \( B(H) \). Moreover, it is proved in [6] that Šemrl’s definition is a proper extension of Hartwig’s definition of the minus partial order of matrices. Also, in [5], the minus partial order is generalized on Banach space operators which have generalized inverses.

We prove the following result, which allows us to consider the algebraic version of the minus partial order. First, we need the following auxiliary statement.
Lemma 1.1. Let $H, K, L, N, N \neq \{0\}$ be Hilbert spaces, $A_1 \in \mathcal{L}(H, L)$ and $A_2 \in \mathcal{L}(K, L)$. Then the following statements are equivalent:

1. For every $B \in \mathcal{L}(L, N)$ the following equivalence holds:
\[(BA_1 = 0 \text{ and } BA_2 = 0) \text{ if and only if } B = 0;\]
2. \[\mathcal{R}(A_1) + \mathcal{R}(A_2) = L.\]

Proof. (1) $\implies$ (2): Suppose that \[\mathcal{R}(A_1) + \mathcal{R}(A_2) \neq L.\] Then there exists a non-trivial closed subspace $L_1$ of $L$, such that \[\mathcal{R}(A_1) + \mathcal{R}(A_2) \oplus L_1 = L.\] Let $B_1 \in \mathcal{L}(L_1, N)$ be any non-zero bounded linear operator, and define $B \in \mathcal{L}(L, N)$ as follows:
\[Bx = \begin{cases} 0, & x \in \mathcal{R}(A_1) + \mathcal{R}(A_2), \\ B_1x, & x \in L_1. \end{cases}\]
Obviously, $B \neq 0$, $BA_1 = 0$ and $BA_2 = 0$.

(2) $\implies$ (1): Obvious. \qed

Definition 1.2. Let $H$ be a Hilbert space and let $A, B \in \mathcal{L}(H)$. Then we write $A \preceq B$ if and only if there exist idempotent operators $P, Q \in \mathcal{L}(H)$ such that the following hold:

1. \[^{\circ}A = \mathcal{L}(H) \cdot (I - P);\]
2. \[^{\circ}A = (I - Q) \cdot \mathcal{L}(H);\]
3. \[PA = PB;\]
4. \[AQ = BQ.\]

Theorem 1.2. The minus partial order given by Definition 1.1 is on $\mathcal{L}(H)$ equivalent to the order given by Definition 1.2.

Proof. Let $A, B \in \mathcal{L}(H)$ and suppose that $A \preceq B$ in the sense of Definition 1.1. Thus, there exist idempotent $P, Q \in (\mathcal{L}(H))^*$ such that $\mathcal{R}(P) = \overline{\mathcal{R}(A)}$, $\mathcal{N}(A) = \mathcal{N}(Q)$, $PA = PB$ and $AQ = BQ$. Let us prove that $A \preceq B$ in the sense of Definition 1.2. It is sufficient to show that \[^{\circ}A = \mathcal{L}(H) \cdot (I - P)\] and \[^{\circ}A = (I - Q) \cdot \mathcal{L}(H).\]

Let $D \in \mathcal{L}(H)$. Then $D(I - P)A = 0$, since $\mathcal{R}(A) \subseteq \mathcal{R}(P) = \mathcal{N}(I - P)$. Thus, $\mathcal{L}(H) \cdot (I - P) \subseteq ^{\circ}A$. On the other hand, suppose that $D \in ^{\circ}A$. Then $DA = 0$ so $\overline{\mathcal{R}(A)} \subseteq \mathcal{N}(D)$ since $\mathcal{N}(D)$ is closed. We obtain $\mathcal{R}(P) \subseteq \mathcal{N}(D)$ and thus we have $DP = 0$. Therefore
\[D = D(P + I - P) = D(I - P) \in \mathcal{L}(H) \cdot (I - P).\]
Hence, \[^{\circ}A = \mathcal{L}(H) \cdot (I - P).\]
If \( D \in \mathcal{L}(H) \), since \( \mathcal{R}(I - Q) = \mathcal{N}(Q) = \mathcal{N}(A) \), we get \( A(I - Q)D = 0 \). Thus, \( (I - Q) \cdot \mathcal{L}(H) \subseteq A^\circ \). On the other hand, let \( D \in A^\circ \). Then \( \mathcal{R}(D) \subseteq \mathcal{N}(A) = \mathcal{N}(Q) \), so \( QD = 0 \). We obtain

\[
D = (Q + I - Q)D = (I - Q)D \in (I - Q) \cdot \mathcal{L}(H).
\]

Therefore, \( A^\circ = (I - Q) \cdot \mathcal{L}(H) \).

Let us now prove that Definition 1.2 implies Definition 1.1. Suppose that \( A \preceq B \), \( A, B \in \mathcal{L}(H) \), in the sense of Definition 1.2. There exist idempotents \( P, Q \in (\mathcal{L}(H))^\bullet \) such that \( \circ A = \mathcal{L}(H) \cdot (I - P) \), \( A^2 = (I - Q) \cdot \mathcal{L}(H) \), \( PA = PB \) and \( AQ = BQ \). It is sufficient to show that \( \mathcal{R}(P) = \mathcal{R}(A) \) and \( \mathcal{N}(A) = \mathcal{N}(Q) \).

From \( \circ A = \mathcal{L}(H) \cdot (I - P) \) we get \( (I - P)A = 0 \), so \( \mathcal{R}(A) \subseteq \mathcal{N}(I - P) = \mathcal{R}(P) \), and consequently \( \mathcal{R}(A) \subseteq \mathcal{R}(P) \), since \( \mathcal{R}(P) \) is closed. Since \( H = \mathcal{R}(P) \oplus \mathcal{N}(P) \), every operator from \( \mathcal{L}(H) \) has a \( 2 \times 2 \) matrix form with respect to this decomposition. Particularly, from \( \mathcal{R}(A) \subseteq \mathcal{R}(P) \), we obtain the following:

\[
A = \begin{bmatrix} A_1 & A_2 \\ 0 & 0 \end{bmatrix} : \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix} \rightarrow \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix}.
\]

Now we use the fact \( \circ A = \mathcal{L}(H) \cdot (I - P) \). Notice that \( C \in \mathcal{L}(H) \cdot (I - P) \) if and only if \( C = C(I - P) \), that is, if and only if \( CP = 0 \). Also,

\[
P = \begin{bmatrix} I_{\mathcal{R}(P)} & 0 \\ 0 & 0 \end{bmatrix} : \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix} \rightarrow \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix}.
\]

If

\[
C = \begin{bmatrix} C_1 & C_2 \\ C_3 & C_4 \end{bmatrix} : \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix} \rightarrow \begin{bmatrix} \mathcal{R}(P) \\ \mathcal{N}(P) \end{bmatrix},
\]

then \( CP = 0 \) is equivalent to \( C_1 = 0 \) and \( C_3 = 0 \). On the other hand, \( CA = 0 \) holds if and only if

\[
\begin{bmatrix} C_1A_1 & C_1A_2 \\ C_3A_1 & C_3A_2 \end{bmatrix} = 0.
\]

So we have the following conclusion. For arbitrary operators \( C_1 \in \mathcal{L}(\mathcal{R}(P)) \) and \( C_3 \in \mathcal{L}(\mathcal{R}(P), \mathcal{N}(P)) \), we have the equivalence:

\[
(C_1A_1 = 0, \ C_1A_2 = 0, \ C_3A_1 = 0, \ C_3A_2 = 0) \iff (C_1 = 0, \ C_3 = 0). \quad (1)
\]

One of the subspaces \( \mathcal{R}(P) \) or \( \mathcal{N}(P) \) is not the zero subspace. Without loss of generality suppose that \( \mathcal{R}(P) \neq \{0\} \). Set \( C_3 = 0 \). Now (1) becomes

\[
(C_1A_1 = 0, \ C_1A_2 = 0) \iff C_1 = 0,
\]
for any \( C_1 \in \mathcal{L}(P) \). From Lemma 1.1 we obtain that \( R(A_1) + R(A_2) = R(P) \). Since \( \mathcal{R}(A) = R(A_1) + R(A_2) \) we have \( \mathcal{R}(A) = R(P) \).

Now, from the condition \( A^o = (I - Q) \cdot \mathcal{L}(H) \), using the result we have just proved, the following hold:

\[
A^o = (I - Q) \cdot \mathcal{L}(H) \iff \circ(A^*) = \mathcal{L}(H) \cdot (I - Q^*) \iff \mathcal{R}(Q^*) = \mathcal{R}(A^*)
\]

\[
\iff \mathcal{R}(I - Q) = \mathcal{N}(Q) = \mathcal{N}(A).
\]

Hence, \( A \preceq B \) in the sense of Definition 1.2.

\[\square\]

2. Results in rings

Previous Theorem 1.2 suggests the following definition of the minus partial order. Since some preliminary results can be proved in a general setting, we shall in this section use that \( \mathcal{A} \) is a ring with the unit 1.

**Definition 2.1.** Let \( \mathcal{A} \) be a ring with the unit 1, and let \( a, b \in \mathcal{A} \). Then we write \( a \preceq b \) if and only if there exists idempotents \( p, q \in \mathcal{A}^* \) such that the following hold:

1. \( \circ a = \mathcal{A}(1 - p) \);
2. \( a^o = (1 - q)\mathcal{A} \);
3. \( pa = pb \);
4. \( aq = bq \).

We call \( \preceq \) the minus partial order on \( \mathcal{A} \). In the next section we will prove that when \( \mathcal{A} \) is a Rickart ring, \( \preceq \) is indeed a partial order.

Notice that from (1) we obtain \( (1 - p)a = 0 \) so \( a = pa \). Similarly, \( a = aq \).

We need some auxiliary results.

**Lemma 2.1.** Let \( p, q \in \mathcal{A}^* \). Then

1. \( \mathcal{A}(1 - p) = \circ p \);
2. \( (1 - q)\mathcal{A} = q^o \).

**Proof.** We have \( \mathcal{A}(1 - p) \subseteq \circ p \), since \( (1 - p)p = 0 \). Suppose that for \( u \in \mathcal{A} \), \( up = 0 \). Then \( u = u(1 - p) \in \mathcal{A}(1 - p) \). The proof of (ii) is similar.

\[\square\]

It follows that we can replace the conditions (1) and (2) of Definition 2.1 by the conditions \( \circ a = \circ p \) and \( a^o = q^o \) respectively.

**Lemma 2.2.** Let \( p \in \mathcal{A}^* \) and \( a \in \mathcal{A} \). Then
(1) \((\circ p)^\circ = pA\);
(2) \(\circ a = A(1 - p) \iff (\circ a)^\circ = (\circ p)^\circ\).

**Proof.** (1): By Lemma 2.1,

\[(\circ p)^\circ = (A(1 - p))^\circ = \{ u \in A : (\forall x \in A) \ x(1 - p)u = 0 \}\]

\[= \{ u \in A : (1 - p)u = 0 \} = pA.\]

(2): If \(\circ a = A(1 - p)\) then \((\circ a)^\circ = (\circ p)^\circ\) by Lemma 2.1. Now, suppose that \((\circ a)^\circ = (\circ p)^\circ\) i.e. \((\circ a)^\circ = pA\). Let \(u \in \circ a\). As \(p \in pA = (\circ a)^\circ\) we have \(up = 0\) so \(u = u(1 - p) \in A(1 - p)\). On the other hand, suppose that \(u \in A(1 - p)\) i.e. \(up = 0\). As \(a \in (\circ a)^\circ = pA\) we have \(a = pa\) so \(ua = upa = 0\). \(\square\)

In the same manner we obtain the following lemma.

**Lemma 2.3.** Let \(q \in A^*\) and \(a \in A\). Then

(i) \(\circ(q^\circ) = Aq\);
(ii) \(a^\circ = (1 - q)A \iff \circ(a^\circ) = \circ(q^\circ)\).

It follows that we can replace the conditions (1) and (2) of Definition 2.1 by the conditions \((\circ a)^\circ = pA\) and \(\circ(a^\circ) = Aq\) respectively.

Our definition of order \(\preceq\) is a proper extension of well known partial order on the set of idempotents.

**Theorem 2.4.** Let \(a, b \in A^*\). Then \(a \preceq b\) if and only if \(ab = ba = a\).

**Proof.** Suppose that \(a, b \in A^*\) and \(ab = ba = a\). By Lemma 2.1 we have \(\circ a = A(1 - a)\), \(a^\circ = (1 - a)A\) and by assumption \(aa = ab, aa = ba\) so \(a \preceq b\). Now suppose that \(a \preceq b\). There exist \(p, q \in A^*\) as in Definition 2.1 so \(ab = (pa)b = (pb)b = pb = a\) and \(ba = b(aq) = b(bq) = bq = a\). \(\square\)

Recall that von Neumann regular ring is a ring \(A\) such that for every \(a \in A\) there exists an \(x \in A\) such that \(axa = a\). The following theorem shows that, when \(A\) is a von Neumann regular ring, \(\preceq\) order coincides with well known minus partial order which is defined by \(a \preceq b\) if there exists an \(x \in A\) such that \(ax = bx\) and \(xa = xb\) where \(axa = a\). Thus, the minus partial order in von Neumann regular ring is defined in the same way as in \(L(H)\) where \(H\) is a finite dimensional Hilbert space.

**Theorem 2.5.** Suppose that \(A\) is a von Neumann regular ring with the unit 1 and let \(a, b \in A\). Then \(a \preceq b\) if and only if \(a \preceq b\).
Proof. Suppose that \( a \leq b \) and let \( p, q \in A^* \) be as in Definition 2.1. Since \( A \) is von Neumann regular ring, there exists an \( x \in A \) such that \( axa = a \). Set \( y = qxp \). We have \( aya = a(qxp)a = axa = a, ay = aqxp = bqxp = by, \) \( ya = qxp(a) = yb \) so \( a \leq b \).

Now suppose that \( a \leq b \). There exists an \( x \in A \) such that \( axa = a \), \( ax = bx \), \( xa = xb \). Set \( p = ax \) and \( q = xa \). Then \( p \in A^* \) and \( 1 - p \in \mathfrak{o}A \). On the other hand if \( u \in \mathfrak{o}A \) then \( up = u(ax) = 0 \), so \( u = u(1 - p) \), \( \mathfrak{o}A = A(1 - p) \). Moreover, \( pa = axa = axb = pb \). Similarly, \( q \in A^* \), \( a^2 = (1 - q)A, aq = bq \), so \( a \leq b \).

Since we can not use decompositions of spaces induced by projections, we have to use idempotents appropriately.

Remark 2.1. We say that equality \( 1 = e_1 + e_2 + \cdots + e_n \), where \( e_1, e_2, \ldots, e_n \in A^* \), is a decomposition of the identity of the ring \( A \) if \( e_i \) and \( e_j \) are orthogonal for \( i \neq j \), i.e. \( e_ie_j = 0 \) for \( i \neq j \). Let \( 1 = e_1 + \cdots + e_n \) and \( 1 = f_1 + \cdots + f_n \) be two decompositions of the identity of a ring \( A \). For any \( x \in A \) we have

\[
x = 1 \cdot x \cdot 1 = (e_1 + \cdots + e_n)x(f_1 + \cdots + f_n) = \sum_{i,j=1}^n e_i x f_j,
\]

and above sum defines a decomposition of \( A \) into a direct sum of groups:

\[
A = \bigoplus_{i,j=1}^n e_i A f_j,
\]

(2)

It is convenient to write \( x \) as a matrix

\[
x = \begin{bmatrix}
x_{11} & \cdots & x_{1n} \\
\vdots & \ddots & \vdots \\
x_{n1} & \cdots & x_{nn}
\end{bmatrix}_{e_i f_j},
\]

where \( x_{ij} = e_i x f_j \in e_i A f_j \).

If \( x = (x_{ij})_{e \times f} \) and \( y = (y_{ij})_{e \times f} \), then it is obvious that \( x + y = (x_{ij} + y_{ij})_{e \times f} \). Moreover, if \( 1 = g_1 + \cdots + g_n \) is a decomposition of the identity of \( A \) and \( z = (z_{ij})_{f \times g} \), then, by the orthogonality of idempotents involved, \( xz = (\sum_{k=1}^n x_{ik} z_{kj})_{e \times g} \). Thus, if we have decompositions of the identity of \( A \), then the usual algebraic operations in \( A \) can be interpreted as simple operations between appropriate \( n \times n \) matrices over \( A \).

When \( e_i = f_i, i = 1, n \), the decomposition (2) is known as the two-sided Peirce decomposition of the ring \( A \). [4]. When \( n = 2, e_1 = p \) and \( f_1 = q \) then we write

\[
x = \begin{bmatrix}
x_{11} & x_{12} \\
x_{21} & x_{22}
\end{bmatrix}_{p \times q}
\]
We prove the following result.

**Theorem 2.6.** Let $\mathcal{A}$ be a ring with the unit, and let $a, b \in \mathcal{A}$. Then $a \preceq b$ if and only if there exists idempotents $p, q \in \mathcal{A}^*$ such that the following three conditions hold:

1. $a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q}$ and $b = \begin{bmatrix} a_1 & 0 \\ 0 & b_1 \end{bmatrix}_{p \times q}$;
2. If $z \in \mathcal{A}p$ and $za_1 = 0$, then $z = 0$;
3. If $z \in q\mathcal{A}$ and $a_1z = 0$, then $z = 0$.

**Proof.** Suppose that $a \preceq b$ and let $p, q \in \mathcal{A}^*$ be corresponding idempotents. As we have seen $a = pa = aq = paq$, so

$$a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q}.$$ 

Let

$$b = \begin{bmatrix} b_4 & b_2 \\ b_3 & b_1 \end{bmatrix}_{p \times q}.$$ 

From $p(b - a) = 0$ we get

$$\begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} \begin{bmatrix} b_4 - a_1 & b_2 \\ b_3 & b_1 \end{bmatrix}_{p \times q} = \begin{bmatrix} p(b_4 - a_1) & pb_2 \\ 0 & 0 \end{bmatrix}_{p \times q} = 0,$$

implying that $p(b_4 - a_1) = 0$ and $pb_2 = 0$. Since $pa_1 = a_1$, $pb_4 = b_4$, and $pb_2 = b_2$, we get $a_1 = b_4$ and $b_2 = 0$. Analogously, from $(b - a)q = 0$ we get $b_3 = 0$. Thus, the statement (1) of this theorem is proved.

In order to prove the statement (2), suppose that $z \in \mathcal{A}p$ and $za_1 = 0$. Since $a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q}$, we get $za = 0$, so $z \in \mathcal{A}(1 - p) = \mathcal{A}p$, i.e. $z = zp = 0$. The statement (3) can be proved proved in the same manner.

Now, we suppose that there exists idempotents $p, q \in \mathcal{A}^*$ such that statements (1)--(3) of this theorem hold. We immediately obtain

$$p(a - b) = \begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} \begin{bmatrix} 0 & 0 \\ 0 & -b_1 \end{bmatrix}_{p \times q} = 0 \quad \text{and} \quad (a - b)q = \begin{bmatrix} 0 & 0 \\ 0 & -b_1 \end{bmatrix}_{p \times q} \begin{bmatrix} q & 0 \\ 0 & 0 \end{bmatrix}_{q \times q} = 0.$$ 

Now, we prove that $\mathcal{A} = \mathcal{A}(1 - p)$. If $y \in \mathcal{A}(1 - p)$, then $y = \begin{bmatrix} 0 & y_2 \\ y_1 & 0 \end{bmatrix}_{q \times p}$. It is easy to see that $ya = 0$. Thus, we established $\mathcal{A}(1 - p) \subseteq \mathcal{A}$. 
To prove the opposite inclusion, suppose that \(z \in \mathfrak{a}a\). Then \(z = \begin{bmatrix} z_1 & z_2 \\ z_3 & z_4 \end{bmatrix}_{q \times q}\) and
\[
0 = za = \begin{bmatrix} z_1 a_1 & 0 \\ z_3 a_1 & 0 \end{bmatrix}_{q \times q}.
\]
We conclude \(z_1 a_1 = z_3 a_1 = 0\). Since \(z_1, z_3 \in \mathcal{A}p\), (2) shows that \(z_1 = z_3 = 0\). Thus, \(z = \begin{bmatrix} 0 & z_2 \\ 0 & z_4 \end{bmatrix}_{q \times q} \in \mathcal{A}(1-p)\). Hence, we proved \(\mathfrak{a}a \subseteq \mathcal{A}(1-p)\).

In the same manner we can prove that \(a^\circ = (1-q)\mathcal{A}\). \(\square\)

3. The minus partial order in Rickart rings

The idempotents in Definition 2.1 need not be unique. Write
\[
\begin{align*}
\text{LP}(a) & := \{ p \in \mathcal{A}^* : a^\circ a = \mathcal{A}(1-p) \}, \\
\text{RP}(a) & := \{ q \in \mathcal{A}^* : a^\circ = (1-q)\mathcal{A} \}.
\end{align*}
\]
When \(\mathcal{A}\) is Rickart ring then \(\text{LP}(a)\) and \(\text{RP}(a)\) are nonempty. Lemma 2.1 gives characterizations \(\text{LP}(a) = \{ p \in \mathcal{A}^* : a^\circ p = \mathcal{A}(1-p) \}\) and \(\text{RP}(a) = \{ q \in \mathcal{A}^* : a^\circ = q^\circ \}\).

**Lemma 3.1.** Let \(a \in \mathcal{A}, \ p \in \text{LP}(a)\) and \(q \in \text{RP}(a)\). (Such idempotents exist if \(\mathcal{A}\) is a Rickart ring.) Then
\[
\begin{align*}
(1-p)a & = a(1-q) \\
\text{PROOF.} & \text{ From } (1-p)a = 0 = a(1-q) \text{ we conclude that } a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q}. \text{ If } p' = \begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} \text{ then } p'^2 = p'. \text{ Since } 1 = \begin{bmatrix} p & 0 \\ 0 & 1-p \end{bmatrix}_{p \times p} \text{ we also have }
\end{align*}
\]
\[
\begin{align*}
(1-p')a & = \begin{bmatrix} 0 & -p_1 \\ 0 & 1-p \end{bmatrix}_{p \times p} \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q} = 0. \tag{3}
\end{align*}
\]
If \(u = \begin{bmatrix} u_1 & u_2 \\ u_3 & u_4 \end{bmatrix}_{p \times p} \in a^\circ\) then \(u_1 a = 0\) and \(u_3 a = 0\) so \(u_1 = u_1 p = 0\) and \(u_3 = u_3 p = 0\). On the other side, if \(u_1 = 0\) and \(u_3 = 0\) then it is clear that \(ua = 0\).

From \(\begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} \begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} = 0\) we conclude \(a^\circ \subseteq p'\). Now, (3) and Lemma 2.1 give \(a^\circ = \mathcal{A}(1-p')\), that is \(p' \in \text{LP}(a)\).

Suppose now that \(p' = \begin{bmatrix} p & p_1 \\ 0 & 0 \end{bmatrix}_{p \times p} \in \text{LP}(a)\). Then \(a^\circ p' = a = a^\circ\), so
\[
0 = (1-p')p = \begin{bmatrix} p & -p_2 \\ -p_3 & 1-p-p_4 \end{bmatrix}_{p \times p} \begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} = \begin{bmatrix} p & 0 \\ 0 & 0 \end{bmatrix}_{p \times p} = 0.
\]
and hence $p_2 = p$ and $p_3 = 0$. From $a \leq p'$ it follows

\[
0 = \begin{bmatrix} 0 & u_2 \\ 0 & u_4 \end{bmatrix}_{p \times p} \begin{bmatrix} p & p_1 \\ 0 & p_4 \end{bmatrix}_{p \times p} = \begin{bmatrix} 0 & u_2 p_4 \\ 0 & u_4 p_4 \end{bmatrix}_{p \times p},
\]

so $u_4 p_4 = 0$, for every $u_4 \in (1 - p)A(1 - p)$. Setting $u_4 = 1 - p$ we get $p_4 = 0$.

Thus, the statement (1) of the theorem is proved. In the same manner we can prove the statement (2). □

**Corollary 3.2.** Let $a, b \in A$. Suppose that $a \preceq b$ and let $p, q \in A^*$ be corresponding idempotents. Then

\[
\{p' \in \text{LP}(a) : a = p'b\} = \left\{ \begin{bmatrix} p & p_1 \\ 0 & 0 \end{bmatrix}_{p \times p} : p_1 \in pA(1 - p), p_1 b_1 = 0 \right\}
\]

\[
\{q' \in \text{RP}(a) : a = b q'\} = \left\{ \begin{bmatrix} q & 0 \\ q_1 & 0 \end{bmatrix}_{q \times q} : q_1 \in (1 - q)Aq, b_1 q_1 = 0 \right\}, \quad (4)
\]

where $b_1$ is as in Theorem 2.6.

**Proof.** We will prove only the equality (4); the proof of the other one is analogous. Since $a \preceq b$, Theorem 2.6 gives

\[
a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q}, \quad b = \begin{bmatrix} a_1 & 0 \\ 0 & b_1 \end{bmatrix}_{p \times q}.
\]

If $p'$ belongs to the set on the right hand side of (4) then, by Lemma 3.1, $p' \in \text{LP}(a)$. Also,

\[
p'b = \begin{bmatrix} p & p_1 \\ 0 & 0 \end{bmatrix}_{p \times p} \begin{bmatrix} a_1 & 0 \\ 0 & b_1 \end{bmatrix}_{p \times q} = \begin{bmatrix} a_1 & p_1 b_1 \\ 0 & 0 \end{bmatrix}_{p \times q} = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q} = a.
\]

To prove the opposite inclusion, suppose that $p' \in \text{LP}(a)$ and $a = p'b$. Lemma 3.1 leads to $p = \begin{bmatrix} p & p_1 \\ 0 & 0 \end{bmatrix}_{p \times p}$. Now, $a = p'b$ gives

\[
\begin{bmatrix} a_1 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q} = a = p'b = \begin{bmatrix} a_1 & p_1 b_1 \\ 0 & 0 \end{bmatrix}_{p \times q},
\]

so $p_1 b_1 = 0$. □
However, to prove that \( \preceq \) is actually a partial order, we need the assumption that \( \mathcal{A} \) is Rickart ring.

We now prove the main result of this section.

**Theorem 3.3.** Let \( \mathcal{A} \) be a Rickart ring. Then \( \preceq \) is a partial order in \( \mathcal{A} \).

**Proof.** Since \( \mathcal{A} \) is a Rickart ring, for any \( a \in \mathcal{A} \) there exist idempotents \( p, q \in \mathcal{A}^* \), such that \( a = \mathcal{A}(1 - p) \) and \( a^2 = (1 - q)\mathcal{A} \). Now the reflexivity of \( \preceq \) follows.

To prove the antisymmetry, suppose that \( a \preceq b \) and \( b \preceq a \). Then
\[
\begin{bmatrix}
a_1 & 0 \\
0 & 0
\end{bmatrix}_{p \times q}, \quad b = \begin{bmatrix}
a_1 & 0 \\
0 & b_1
\end{bmatrix}_{p \times q}, \tag{5}
\]
and there exist \( r, s \in \mathcal{A}^* \) such that \( b = ra = as \). Let \( r = \begin{bmatrix} r_1 & r_2 \\
r_3 & r_4 \end{bmatrix}_{p \times p} \). We have
\[
\begin{bmatrix}
a_1 & 0 \\
0 & b_1
\end{bmatrix}_{p \times q} = b = ra = \begin{bmatrix}
r_1a_1 & 0 \\
r_3a_1 & 0
\end{bmatrix}_{p \times q},
\]
so \( b_1 = 0 \) and hence \( a = b \).

We have to show transitivity. Let \( a \preceq b \) and \( b \preceq c \). Then there exist idempotents \( p, q, r, s \in \mathcal{A}^* \) such that \( a \) and \( b \) have the matrix forms as in (5), \( a_1 = \circ p, a_1^2 = q^o \) and \( b = \mathcal{A}(1 - r) = \circ r, b^o = (1 - s)\mathcal{A} = s^o, b = rc = cs \). Suppose that
\[
r = \begin{bmatrix} r_1 & r_2 \\
r_3 & r_4 \end{bmatrix}_{p \times p} \quad \text{and} \quad c = \begin{bmatrix} c_1 & c_2 \\
c_3 & c_4 \end{bmatrix}_{p \times q}.
\]

Since
\[
0 = (1 - r)b = \begin{bmatrix} p - r_1 & -r_2 \\
r_3 & 1 - p - r_4 \end{bmatrix}_{p \times p} \begin{bmatrix} a_1 & 0 \\
0 & b_1 \end{bmatrix}_{p \times q} = \begin{bmatrix} (p - r_1)a_1 & -r_2b_1 \\
r_3a_1 & (1 - p - r_4)b_1 \end{bmatrix}_{p \times q},
\]
\( \circ a_1 = \circ p \) shows that \( 0 = (p - r_1)p = p - r_1 \) and \( 0 = r_3p = r_3 \). Also, \( r_2b_1 = 0 \).

From \( b = rc \) we conclude that
\[
\begin{bmatrix} a_1 & 0 \\
0 & b_1 \end{bmatrix}_{p \times q} = \begin{bmatrix} p & r_2 \\
r_4 & r_4 \end{bmatrix}_{p \times p} \begin{bmatrix} c_1 & c_2 \\
c_3 & c_4 \end{bmatrix}_{p \times q} = \begin{bmatrix} c_1 + r_2c_3 & c_2 + r_2c_4 \\
r_4c_3 & r_4c_4 \end{bmatrix}_{p \times q},
\]
so
\[ a_1 = c_1 + r_2 c_3 \quad \text{and} \quad 0 = c_2 + r_2 c_4. \tag{6} \]
Let \( p' = [p^2 \quad 0 \quad 0]_{p \times p'} \). From Corollary 3.2 it follows that
\[ \circ a = A(1 - p') \quad \text{and} \quad a = p'b. \tag{7} \]
Since,
\[ p'c = \begin{bmatrix} c_1 + r_2 c_3 & c_2 + r_2 c_4 \\ 0 & 0 \end{bmatrix}_{p \times q}, \tag{8} \]
(6) shows that
\[ p'c = a. \tag{9} \]
Similar consideration shows that if \( s = [s_1 \quad s_2]_{q \times q} \) than \( s_1 = q, \quad s_2 = 0 \) and that for \( q' = [q \quad 0 \quad 0 \quad 0]_{q \times q} \) we have
\[ a^\circ = A(1 - q'), \quad a = bq' = cq'. \tag{9} \]
By definition, from (7)–(9) we obtain that \( a \preceq c \). \[ \square \]
Moreover, from the proof of Theorem 3.3 it follows that if \( a \preceq b \) and \( b \preceq c \) then there exist common idempotents \( p' \) and \( q' \) showing that \( a \preceq b \) and \( a \preceq c \).

**Theorem 3.4.** Let \( A \) be a Rickart ring and \( a, b \in A \). Then \( a \preceq b \) if and only if there exist decompositions of the identity of the ring \( A \)
\[ 1 = e_1 + e_2 + e_3, \quad 1 = f_1 + f_2 + f_3 \]
such that the following five conditions hold:
(1) \( a = \begin{bmatrix} a_1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}_{e \times f} \) and \( b = \begin{bmatrix} a_1 & 0 & 0 \\ 0 & b_1 & 0 \\ 0 & 0 & 0 \end{bmatrix}_{e \times f} \);
(2) If \( z \in A e_1 \) and \( za_1 = 0 \), then \( z = 0 \);
(3) If \( z \in f_1 A \) and \( a_1 z = 0 \), then \( z = 0 \);
(4) If \( z \in A e_2 \) and \( zb_1 = 0 \), then \( z = 0 \);
(5) If \( z \in f_2 A \) and \( b_1 z = 0 \), then \( z = 0 \).

**Proof.** “If” part follows from Theorem 2.6. Now, suppose that \( a \preceq b \). By Theorem 2.6 we have
\[ a = \begin{bmatrix} a_1 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}_{p \times q} \quad \text{and} \quad b = \begin{bmatrix} a_1 & 0 \\ 0 & b_1 \end{bmatrix}_{p \times q}, \]
such that \( z = 0 \) whenever \( z \in \mathcal{A}p \) and \( za_1 = 0 \), and \( z = 0 \) whenever \( z \in qA \) and \( a_1z = 0 \). \( \mathcal{A} \) is a Rickart ring so there exist \( r, s \in \mathcal{A}^* \) such that \( \circ b_1 = \mathcal{A}(1 - r) = \circ r \) and \( b_1^2 = (1 - s)A = s^2 \). Notice that \( pr = 0 \). Indeed, since \( b_1 \in (1 - p)\mathcal{A}(1 - q) \), we have \( pb_1 = 0 \) and therefore \( p \in \circ b_1 = \circ r \). Let \( r':= r-\circ r p (1 - r) = r - \circ r p = r(1 - p) \).

We have \( r' \in \mathcal{A}^* \) since \( r'^2 = (r - \circ r p)(r - \circ r p) = r - \circ r p = r' \). Our next claim is that \( \circ b_1 = \circ r' \). If \( ur = 0 \) then \( ur' = 0 \). On the other hand, \( (1 - r')b_1 = (1 - r + \circ r p)b_1 = 0 \), due to \( b_1 = \circ r b_1 \). Thus

\[
\circ b_1 = \circ r' = \mathcal{A}(1 - r').
\]

Next, \( pr = 0 \) implies \( pr' = 0 \). Moreover, \( r'p = r(1 - p)p = 0 \). Set \( e_1 = p \), \( e_2 = r' \), and \( e_3 = 1 - p - r' \). Then \( 1 = e_1 + e_2 + e_3 \) is decomposition of the identity of the ring \( \mathcal{A} \) and from (10) it follows that \( zb_1 = 0 \) implies \( z = 0 \) when \( z \in \mathcal{A}c_2 \).

Now, set \( f_1 = q \), \( f_2 = (1 - q)s \) and \( f_3 = 1 - f_1 - f_2 \). With similar consideration we can show that \( 1 = f_1 + f_2 + f_3 \) is the decomposition of the identity of the ring \( \mathcal{A} \) and that condition (5) of this theorem holds. Of course, statements (2) and (3) are satisfied by Theorem 2.6 since \( e_1 = p \) and \( f_1 = q \). As \( \circ b_1 = \mathcal{A}(1 - r) \) and \( b_1^2 = (1 - s)A \), we have \( e_2bf_2 = r(1 - p)b(1 - q)s = rb_1s = b_1 \). The statement (1) is proved.

Note that the statements (1)–(5) of the previous theorem are equivalent to

\[
e_1 \in \text{LP}(a), \quad e_2 \in \text{LP}(b - a), \quad f_1 \in \text{RP}(a), \quad f_2 \in \text{RP}(b - a).
\]

**Corollary 3.5.** Suppose that \( \mathcal{A} \) is a Rickart ring and \( a, b \in \mathcal{A} \). Then \( a \preceq b \) if and only if \( b - a \preceq b \).

We give one more characterization of minus partial order.

**Theorem 3.6.** Let \( \mathcal{A} \) be a Rickart ring and \( a, b \in \mathcal{A} \). Then \( a \preceq b \) if and only if there exists idempotents \( e_1 \in \text{LP}(a), e_2 \in \text{LP}(b - a), f_1 \in \text{RP}(a), f_2 \in \text{RP}(b - a) \) such that \( e_1e_2 = 0 \) and \( f_2f_1 = 0 \).

**Proof.** The “only if” part follows from Theorem 3.4. In order to prove “if” part suppose that \( e_1 \in \text{LP}(a), e_2 \in \text{LP}(b - a) \) and \( e_1e_2 = 0 \). Then \( e_1a = a \) and \( e_1b = e_1a + e_1(b - a) = a + e_1e_2(b - a) = a \). Similarly, from \( f_2f_1 = 0 \) where \( f_1 \in \text{RP}(a), f_2 \in \text{RP}(b - a) \) it follows that \( af_1 = a \) and \( bf_1 = af_1 + (b - a)f_1 = a + (b - a)f_2f_1 = a \). By definition, \( a \preceq b \).

We conclude this section with the following remark.
Remark 3.1. Suppose that $a \preceq b$ and let us follow the notation of Theorem 3.4. Let us prove that
\[ e_1 + e_2 \in \text{LP}(b) \quad \text{and} \quad f_1 + f_2 \in \text{RP}(b), \]
i.e. $\circ(e_1 + e_2) = \circ b$ and $(f_1 + f_2)\circ = b\circ$. From (1) of Theorem 3.4 it follows that $b = (e_1 + e_2)b$ so $z(e_1 + e_2) = 0$ implies $zb = 0$. On the other hand suppose that $z = [z_{ij}]_{e \times e} \in \circ b$. Then
\[ 0 = zb = \begin{bmatrix} z_{11}a_1 & z_{12}b_1 & 0 \\ z_{21}a_1 & z_{22}b_1 & 0 \\ z_{31}a_1 & z_{32}b_1 & 0 \end{bmatrix}_{e \times f}. \]
By Theorem 3.4 we obtain that $z_{11} = z_{12} = z_{21} = z_{22} = z_{31} = z_{32} = 0$. Now it is easy to see that $z(e_1 + e_2) = 0$. Similarly we can show that $(f_1 + f_2)\circ = b\circ$.

We next show that $e_1 A \cap e_2 A = \{0\}$, $A f_1 \cap A f_2 = \{0\}$ and
\[ (e_1 + e_2) A = e_1 A + e_2 A \quad \text{and} \quad A (f_1 + f_2) = A f_1 + A f_2. \]
First, as we know $e_1 e_2 = e_2 e_1 = 0$. Now if $e_1 x = e_2 y$ for some $x, y \in A$ then $e_1 x = e_1 e_1 x = e_1 e_2 y = 0$. It is clear that $(e_1 + e_2) A \subseteq e_1 A + e_2 A$. Finally, for $x, y \in A$ we have $e_1 x + e_2 y = (e_1 + e_2)(e_1 x + e_2 y)$ so $(e_1 + e_2) A = e_1 A + e_2 A$. In the same manner we can show that $A f_1 \cap A f_2 = \{0\}$ and $A (f_1 + f_2) = A f_1 + A f_2$.

We have no proof for the opposite implication:
If there exist $e_1 \in \text{LP}(a)$, $e_2 \in \text{LP}(b - a)$, $e_3 \in \text{LP}(b)$, $f_1 \in \text{RP}(a)$, $f_2 \in \text{RP}(b - a)$, $f_3 \in \text{RP}(b)$ and if $e_1 A \cap e_2 A = \{0\}$, $A f_1 \cap A f_2 = \{0\}$ and
\[ e_3 A = e_1 A + e_2 A \quad \text{and} \quad A f_3 = A f_1 + A f_2, \]
then $a \preceq b$. Therefore we suggest treating it as an open problem.

ACKNOWLEDGMENT. The authors would like to thank the reviewer for constructive comments that improved the presentation of the paper.
