On the diophantine equation $x^2 + p^2 = y^n$

By MAOHUA LE (Zhanjiang and Shanghai)

Abstract. Let $p$ be an odd prime. In this paper we give some formulas for all positive integer solutions $(x, y, n)$ of the title equation with $n > 2$. Moreover, we completely determine all solutions of the title equation for $p < 100$.

1. Introduction

Let $\mathbb{Z}$, $\mathbb{N}$ be the sets of all integers and positive integers respectively. Let $p$ be a prime. The solutions $(x, y, n)$ of the equation

$$x^2 + p^2 = y^n, \quad x, y, n \in \mathbb{N}, \quad \gcd(x, y) = 1, \quad n > 2$$

have been investigated in many papers. In this respect, Nagell [8] proved that if $p = 2$, then (1) has only the solution $(x, y, n) = (11, 5, 3)$. Ljunggren [4] proved that if $p$ is an odd prime satisfying $p^2 - 1 = 2^{2^r + 1} s$, where $r, s$ are positive integers with $2 \nmid s$, then (1) has only finitely many solutions $(x, y, n)$. Ljunggren’s result in [4] is incomplete as he himself points out in [5]. For instance, the case $p = 5$ remained and remains unsolved.

In this paper we give some formulas for all solutions $(x, y, z)$ of (1).

Mathematics Subject Classification: 11D61.

Key words and phrases: exponential diophantine equation.

We now introduce some notations. For any positive integers $m$ and $s$, let

\begin{align*}
  f(m) &= \sum_{i=0}^{[m/2]} \binom{m}{2i} 2^{m-2i}i^3, \\
  \bar{f}(m) &= \sum_{i=0}^{[(m-1)/2]} \binom{m}{2i+1} 2^{m-2i-1}i^3, \\
  g(m) &= \sum_{i=0}^{[m/2]} \binom{m}{2i} 2^i, \\
  \bar{g}(m) &= \sum_{i=0}^{[(m-1)/2]} \binom{m}{2i+1} 2^i, \\
  h(m, s) &= \sum_{i=0}^{[m/2]} (-1)^i \binom{m}{2i} (2s)^{m-2i}, \\
  \bar{h}(m, s) &= \sum_{i=0}^{[(m-1)/2]} (-1)^i \binom{m}{2i+1} (2s)^{m-2i-1}.
\end{align*}

We prove a general result as follows.

**Theorem.** Let $p$ be an odd prime. If $(x, y, n)$ is a solution of (1), then it satisfies one of the following conditions:

(I) $p = f(2^r), (x, y, n) = (8\bar{f}(2^r)^3 + 3\bar{f}(2^r)^2f(2^r)^2 + \bar{f}(2^r)^2, 3)$, where $r$ is a positive integer.

(II) $p = g(q), (x, y, n) = ((g(q)^2 - 1)/2, \bar{g}(q), 4)$, where $q$ is an odd prime.

(III) $p = 239, (x, y, z) = (28560, 13, 8)$.

(IV) $p = |h(q, s)|, (x, y, n) = (|h(q, s)|, 4s^2 + 1, q)$, where $q$ is an odd prime, $s$ is a positive integer.

Using the above theorem, we can completely determine all solutions of (1) for some small $p$.

**Corollary.** If $p$ is an odd prime with $p < 100$, then (1) has only the following solutions:

(i) $p = 7, (x, y, n) = (24, 5, 4), (524, 65, 3)$. 
On the diophantine equation \( x^2 + p^2 = y^n \)

(ii) \( p = 11, (x, y, n) = (2, 5, 3) \).

(iii) \( p = 29, (x, y, n) = (278, 5, 7) \).

(iv) \( p = 41, (x, y, n) = (38, 5, 5), (840, 29, 4) \).

(v) \( p = 47, (x, y, n) = (52, 17, 3) \).

(vi) \( p = 97, (x, y, n) = (1405096, 12545, 3) \).

As an interesting example, we see from the above corollary that if \( p = 5 \), then (1) has no solutions \((x, y, n)\).

2. Preliminaries

**Lemma 1** ([7, pp. 120–122]). Let \( n \) be an odd integer with \( n > 1 \). Every solution \((X, Y, Z)\) of the equation

\[
X^2 + Y^2 = Z^n, \quad X, Y, Z \in \mathbb{N}, \quad \gcd(X, Y) = 1, \quad (5)
\]

can be expressed as

\[
Z = X_1^2 + Y_1^2, \quad X + Y\sqrt{-1} = (\lambda_1 X_1 + \lambda_2 Y_1\sqrt{-1})^n, \quad \lambda_1, \lambda_2 \in \{-1, 1\},
\]

where \( X_1, Y_1 \) are coprime positive integers.

**Lemma 2** ([3]). The equation

\[
X^2 - 2Y^4 = -1, \quad X, Y \in \mathbb{N} \quad (6)
\]

has only the solutions \((X, Y) = (1, 1)\) and \((239, 13)\).

**Lemma 3** ([2]). The equation

\[
4X^4 - 5Y^2 = -1, \quad X, Y \in \mathbb{N} \quad (7)
\]

has only the solution \((X, Y) = (1, 1)\).

**Lemma 4** ([9]). The equation

\[
1 + X^2 = 2Y^n, \quad X, Y, n \in \mathbb{N}, \quad X > 1, \quad Y > 1, \quad n > 2, \quad 2 \nmid n \quad (8)
\]

has no solutions \((X, Y, n)\).
Lemma 5. Let $m$, $s$ be positive integers, and let $\bar{h}(m, s)$ be defined as in (4). If

$$2s \geq \text{ctg} \frac{\pi}{m+1},$$

then

$$\bar{h}(m, s) \geq (4s^2 + 1)^{(m-1)/2}.\tag{10}$$

Proof. Let

$$\alpha = 2s + \sqrt{-1}, \quad \beta = 2s - \sqrt{-1}.\tag{11}$$

Then there exist a real number $\theta$ such that

$$\alpha = \sqrt{t}e^{\theta \sqrt{-1}}, \quad \beta = \sqrt{t}e^{-\theta \sqrt{-1}}, \quad t = 4s^2 + 1,\tag{12}$$

$$\text{tg} \theta = \frac{1}{2s}, \quad 0 < \theta < \frac{\pi}{2}.\tag{13}$$

By (4), (11) and (12), we get

$$\bar{h}(m, s) = \frac{\alpha^m - \beta^m}{\alpha - \beta} = \frac{t^{(m-1)/2}\sin(m\theta)}{\sin \theta}.\tag{14}$$

If (9) holds, then from (13) we obtain

$$\text{tg} \theta = \frac{1}{2s} \leq \text{tg} \frac{\pi}{m+1}.\tag{15}$$

Since $0 < \theta < \pi/2$ and $0 < \pi/(m+1) \leq \pi/2$, we see from (15) that $\theta \leq \pi/(m+1)$, whence we get

$$m\theta \leq \pi - \theta.\tag{16}$$

Since $0 < \theta < m\theta$ and $\sin(\pi - \theta) = \sin \theta$, we get from (16) that $\sin(m\theta) \geq \sin \theta$. Thus, by (14), we obtain (10). The lemma is proved. \(\square\)

Let $\alpha, \beta$ be algebraic integers. If $\alpha + \beta$ and $\alpha\beta$ are nonzero coprime integers and $\alpha/\beta$ is not a root of unity, then $(\alpha, \beta)$ is called a Lucas pair. Further, let $a = \alpha + \beta$ and $c = \alpha\beta$. Then we have

$$\alpha = \frac{1}{2} \left( a + \lambda \sqrt{b} \right), \quad \beta = \frac{1}{2} \left( a - \lambda \sqrt{b} \right), \quad \lambda \in \{-1, 1\},\tag{17}$$

where $b = a^2 - 4c$. Such pair $(a, b)$ is called the parameters of Lucas pair $(\alpha, \beta)$. Two Lucas pairs $(\alpha_1, \beta_1)$ and $(\alpha_2, \beta_2)$ are equivalent if $\alpha_1/\alpha_2 = \beta_1/\beta_2$. \}
On the diophantine equation $x^2 + p^2 = y^n$ \[ \beta_1 / \beta_2 = \pm 1. \] Given a Lucas pair $(\alpha, \beta)$, one defines the corresponding sequence of Lucas numbers by 
\[ u_m = u_m(\alpha, \beta) = \frac{\alpha^m - \beta^m}{\alpha - \beta}, \quad m = 0, 1, 2, \ldots. \] (18)

For equivalent Lucas pairs $(\alpha_1, \beta_1)$ and $(\alpha_2, \beta_2)$, we have 
\[ u_m(\alpha_1, \beta_1) = \pm u_m(\alpha_2, \beta_2) \]
for any $m \geq 0$.

**Lemma 6.** If $m > 1, 2 \nmid m, a = 2s$ and $b = -4$, where $s$ is a positive integer, then $u_m(\alpha, \beta) \neq \pm 1$.

**Proof.** If $u_m(\alpha, \beta) = \pm 1$, then from (17) and (18) we get 
\[ 4s^2 \sum_{i=0}^{(m-3)/2} (-1)^i \binom{m}{2i+1} (4s^2)^{(m-3)/2-i} + (-1)^{m-1/2} = \pm 1. \] (19)

Clearly, the right side of (19) must be $(-1)^{(m-1)/2}$. Since 
\[ \binom{m}{k} = \binom{m}{m-k}, \quad k = 0, 1, \ldots, m, \]
we get from (19) that 
\[ \binom{m}{2} = 4s^2 \sum_{j=2}^{(m-1)/2} (-1)^j \binom{m}{2j} (4s^2)^{j-2}. \] (20)

It implies that $m \equiv 1 \pmod{8}$. Let $2^u \| m - 1$ and $2^v \| j$ for $j = 2, \ldots, (m-1)/2$. Since 
\[ v_j \leq \frac{\log j}{\log 2} \leq j - 1, \quad j = 2, \ldots, \frac{m-1}{2}, \] (21)
we obtain 
\[ \binom{m}{2j} (4s^2)^{j-1} = m(m-1) \binom{m-2}{2j-2} (4s^2)^{j-1} \frac{(4s^2)^{j-1}}{2j(2j-1)} \] (22)
\[ \equiv 0 \pmod{2^{u+j-2}}, \quad j = 2, \ldots, \frac{m-1}{2}. \]
We see from (22) that the right side of (20) is a multiple of $2^u$. However, since 
\[ 2^{u-1} \| \binom{m}{2}, \]
(20) is impossible. Thus, the lemma is proved. \qed
For any positive integer $m$ with $m > 1$, a prime $p$ is a primitive divisor of $u_m(\alpha, \beta)$ if $p \mid u_m$ and $p \nmid bu_1 \cdots u_{m-1}$. A Lucas pair $(\alpha, \beta)$ such that $u_m(\alpha, \beta)$ has no primitive divisors will be called $m$-defective Lucas pair.

**Lemma 7 ([10]).** Let $m$ satisfy $4 < m \leq 30$ and $m \neq 6$. Then, up to equivalence, all parameters of $m$-defective Lucas pairs are given as follows:

(i) $m = 5$, $(a, b) = (1, 5), (1, -7), (2, -40), (1, -11), (1, -15), (12, -76), (12, -1364).

(ii) $m = 7$, $(a, b) = (1, -7), (1, -19).

(iii) $m = 8$, $(a, b) = (2, -24), (1, -7).

(iv) $m = 10$, $(a, b) = (2, -8), (5, -3), (5, -47).

(v) $m = 12$, $(a, b) = (1, 5), (1, -7), (1, -11), (2, -56), (1, -15), (1, -19).

(vi) $m \in \{13, 18, 30\}$, $(a, b) = (1, -7).

**Lemma 8 ([1, Theorem 1.4]).** If $m > 30$, then no Lucas pair is $m$-defective.

**Lemma 9 ([6]).** If $p$ is an odd primitive divisor of $u_m(\alpha, \beta)$, then $p \equiv (b/p) \pmod{m}$, where $(b/p)$ is the Legendre symbol.

### 3. Proof of Theorem

Let $(x, y, n)$ be a solution of (1). Since $p$ is an odd prime, we get $2 \mid x$ and $2 \nmid y$. If $2 \mid n$, then from (1) we get $y^{n/2} + x = p^2$ and $y^{n/2} - x = 1$. It implies that

$$x = \frac{1}{2}(p^2 - 1) \quad (23)$$

and

$$1 + p^2 = 2y^{n/2}. \quad (24)$$

Since $n > 2$, by Lemma 4, (24) is false if $n/2$ has an odd prime divisor. So we have $n = 2^t$, where $t$ is a positive integer with $t > 1$. Further, by Lemma 2, we see from (24) that either $t = 2$ or $t = 3$. When $t = 2$, we
find from (24) that \((u, v) = (p, y)\) is a positive integer solution of the Pell equation

\[ u^2 - 2v^2 = -1, \quad u, v \in \mathbb{Z}. \]  

(25)

Notice that \(1 + \sqrt{2}\) is the fundamental solution of (25) and \(p\) is an odd prime. We get

\[ p + y\sqrt{2} = \left(1 + \sqrt{2}\right)^q, \]  

(26)

where \(q\) is an odd prime. Thus, by (3), (23), (24) and (26), the solution \((x, y, n)\) satisfies the condition (II). When \(t = 3\), by Lemma 2, the solution \((x, y, n)\) satisfies the condition (III).

By Lemma 1, if \(2 \nmid n\), then from (1) we get

\[ x + p\sqrt{-1} = (\lambda_1X_1 + \lambda_2Y_1\sqrt{-1})^n, \quad \lambda_1, \lambda_2 \in \{-1, 1\}, \]  

(27)

where \(X_1, Y_1\) are positive integers satisfying

\[ X_1^2 + Y_1^2 = y, \quad \gcd(X_1, Y_1) = 1. \]  

(28)

From (27), we obtain

\[ x = X_1 \left| \sum_{i=0}^{(n-1)/2} (-1)^i \binom{n}{2i} X_1^{n-2i-1} Y_1^{2i} \right| \]  

(29)

and

\[ p = Y_1 \left| \sum_{i=0}^{(n-1)/2} (-1)^i \binom{n}{2i+1} X_1^{n-2i-1} Y_1^{2i} \right|. \]  

(30)

We see from (30) that either \(Y_1 = 1\) or \(Y_1 = p\). Since \(2 \nmid y\), we get from (28) that \(2 \mid X_1\). So we have

\[ X_1 = 2s, \quad s \in \mathbb{N}. \]  

(31)

If \(n = 3\) and \(Y_1 = p\), then from (30) and (31) we get

\[ p^2 - 3(2s)^2 = 1. \]  

(32)

It implies that \((u', v') = (p, 2s)\) is a positive integer solution of the Pell equation

\[ u'^2 - 3v'^2 = 1, \quad u', v' \in \mathbb{Z}. \]  

(33)
Notice that $2 + \sqrt{3}$ is the fundamental solution of (33) and $p$ is an odd prime. We get
\[ p + 2s\sqrt{3} = \left(2 + \sqrt{3}\right)^{2^r}, \quad r \in \mathbb{N}. \quad (34) \]
Thus, by (2), (28), (29) and (34), the solution $(x, y, n)$ satisfies the condition (I).

If $n = 5$ and $Y_1 = p$, then we have
\[ 5X_1^4 - 10X_1^2p^2 + p^4 = 5(X_1^2 - p^2)^2 - 4p^4 = 1. \quad (35) \]
It implies that $(X, Y) = (p, |X_1^2 - p^2|)$ is a solution of (7). Therefore, by Lemma 3, (35) is impossible.

If $n > 5$ and $Y_1 = p$, let
\[ \alpha_1 = 2s + p\sqrt{-1}, \quad \beta_1 = 2s - p\sqrt{-1}. \quad (36) \]
Then $(\alpha_1, \beta_1)$ is a Lucas pair. Further, let
\[ u_m(\alpha_1, \beta_1) = \frac{\alpha_1^m - \beta_1^m}{\alpha_1 - \beta_1}, \quad m \geq 0 \quad (37) \]
be the corresponding sequence of Lucas numbers. By (30), (31), (36) and (37), we get $u_n(\alpha_1, \beta_1) = \pm 1$. It implies that $u_n(\alpha_1, \beta_1)$ has no primitive divisors. But, by Lemmas 7 and 8, it is impossible.

If $Y_1 = 1$ and $n$ is an odd prime, by (4), (28), (29) and (30), then the solution $(x, y, n)$ satisfies the condition (IV).

If $Y_1 = 1$ and $n$ is not a prime, let $q$ be the least prime divisor of $n$. Then we have $n = qt$, where $t$ is an odd integer with $t \geq q$. Let
\[ \alpha_2 = 2s + \sqrt{-1}, \quad \beta_2 = 2s - \sqrt{-1}, \quad (38) \]
\[ \alpha_3 = (2s + \sqrt{-1})^q, \quad \beta_3 = (2s - \sqrt{-1})^q. \quad (39) \]
Then both $(\alpha_2, \beta_2)$ and $(\alpha_3, \beta_3)$ are Lucas pairs. Further, let
\[ u_m(\alpha_j, \beta_j) = \frac{\alpha_j^m - \beta_j^m}{\alpha_j - \beta_j}, \quad m \geq 0, \quad j = 2, 3 \quad (40) \]
be the corresponding sequences of Lucas numbers, respectively. By (38), (39) and (40), we get
\[ \alpha_3 = k + l\sqrt{-1}, \quad \beta_3 = k - l\sqrt{-1}, \quad (41) \]
On the diophantine equation $x^2 + p^2 = y^n$

where $k, l$ are integers satisfying

$$k = \frac{1}{2}(\alpha_3 + \beta_3) = \frac{1}{2}(\alpha_2^q + \beta_2^q) \equiv 0 \pmod{2}s, \quad (42)$$

$$l = \frac{\alpha_3 - \beta_3}{2\sqrt{-1}} = \frac{\alpha_2^q - \beta_2^q}{2\sqrt{-1}} = \frac{\alpha_2^q - \beta_2^q}{\alpha_2 - \beta_2} = u_q(\alpha_2, \beta_2). \quad (43)$$

Since $Y_1 = 1$, we see from (30), (38), (39) and (40) that

$$p = \left|\frac{\alpha_2^n - \beta_2^n}{\alpha_2 - \beta_2}\right| = \left|\frac{\alpha_2^q - \beta_2^q}{\alpha_2 - \beta_2} \cdot \frac{\alpha_3^t - \beta_3^t}{\alpha_3 - \beta_3}\right| = |u_q(\alpha_2, \beta_2)| |u_t(\alpha_3, \beta_3)|. \quad (44)$$

By (44), we get either

$$|u_q(\alpha_2, \beta_2)| = 1 \quad (45)$$

or

$$|u_q(\alpha_2, \beta_2)| = p. \quad (46)$$

By Lemma 6, we find from (38) that (45) is impossible. If (46) holds, then from (44) we get

$$|u_t(\alpha_3, \beta_3)| = \pm 1. \quad (47)$$

Further, by Lemmas 7 and 8, we see from (41), (42) and (43) that if (47) holds, then $t \leq 5$. By the same argument as in the proof of the case $n = 5$ and $Y_1 = p$, we can prove that (47) is impossible for $t = 5$. So we have $t = 3$. Since $t \geq q$, we get $q = 3$ and $n = 9$. Then, by (38), (40), (43) and (46), we obtain

$$p = l = |u_3(\alpha_2, \beta_2)| = |\alpha_2^2 + \alpha_2\beta_2 + \beta_2^2| \quad (48)$$

$$= |(\alpha_2 + \beta_2)^2 - \alpha_2\beta_2| = |(4s)^2 - (4s^2 + 1)| = 12s^2 - 1.$$

Similarly, by (39)–(41), (47) and (48), we get

$$|u_3(\alpha_3, \beta_3)| = |\alpha_3^2 + \alpha_3\beta_3 + \beta_3^2| = |(\alpha_3 + \beta_3)^2 - \alpha_3\beta_3|$$

$$= |(2k)^2 - (k^2 + p^2)| = |3k^2 - p^2| = 1.$$

This implies that

$$p^2 - 3k^2 = 1. \quad (49)$$
Since $2s | k$ by (42), we get $k = 2sk_1$, where $k_1$ is an integer. Substitute (48) into (49), we get $12s^2 = k_1^2 + 2$, a contradiction. Thus, (1) has no other solutions $(x, y, n)$. The theorem is proved.

4. Proof of Corollary

Let $p$ be an odd prime with $p < 100$. By Theorem, if $(x, y, n)$ is a solution of (1), then it satisfies one of conditions (I), (II) and (IV).

If $(x, y, n)$ satisfies the condition (I), then from (34) we obtain $n = 3$ and

$$100 > p = \frac{1}{2} \left( (2 + \sqrt{3})^{2r} + (2 - \sqrt{3})^{2r} \right) > \frac{1}{2} \left( 2 + \sqrt{3} \right)^{2r}, \quad r \in \mathbb{N},$$

whence we get $r \leq 2$ and

$$(p, x, y) = \begin{cases} (7, 528, 65), & \text{if } r = 1, \\ (97, 1405096, 12545), & \text{if } r = 2. \end{cases} \quad (50)$$

If $(x, y, n)$ satisfies the condition (II), then from (26) we obtain $n = 4$ and

$$100 > p = \frac{1}{2} \left( \left( 1 + \sqrt{2} \right)^q + \left( 1 - \sqrt{2} \right)^q \right),$$

where $q$ is an odd prime. Therefore, by (52), we get $q \leq 5$ and

$$(p, x, y) = \begin{cases} (7, 24, 5), & \text{if } q = 3, \\ (41, 840, 29), & \text{if } q = 5. \end{cases} \quad (53)$$

If $(x, y, n)$ satisfies the condition (IV), then

$$p = |\tilde{h}(q, s)| = |u_q(\alpha_1, \beta_1)|,$$

where $q$ is an odd prime, $\alpha_1, \beta_1$ and $u_q(\alpha_1, \beta_1)$ are defined as in (36) and (37), respectively. Since $q$ is a prime, we see from (54) that $p$ is a primitive prime divisor of $u_q(\alpha_1, \beta_1)$. Therefore, by Lemma 9, we get from (36) that

$$p \equiv (-1)^{(p-1)/2} \pmod{4q}.$$
On the diophantine equation \( x^2 + p^2 = y^n \)

Since \( p < 100 \), we see from (55) that \( q \leq 17 \). Further, by Lemma 5, if

\[
s \geq \begin{cases} 
1, & \text{if } q = 3, 5, \\
2, & \text{if } q = 7, 11, \\
3, & \text{if } q = 13, 17,
\end{cases}
\]

then

\[
100 > p > (4s^2 + 1)^{(q-1)/2}.
\]

By (56) and (57), we get the following solutions

\[
(p, x, y, n) = \begin{cases} 
(11, 2, 5, 3), & \text{if } q = 3, \ s = 1, \\
(47, 52, 17, 3), & \text{if } q = 3, \ s = 2, \\
(41, 38, 5, 5), & \text{if } q = 5, \ s = 1.
\end{cases}
\]

Finally, we check the remaining cases \((q, s) = (7, 1), (11, 1), (13, 1), (17, 1), (13, 2), (17, 2)\) and get the following solution

\[
(p, x, y, n) = (29, 278, 5, 7).
\]

Thus, by (51), (53), (58) and (59), the corollary is proved.

ACKNOWLEDGEMENT. The author would like to thank the referees for their valuable suggestions.
