Title: An estimate for the length of an arithmetic progression the product of whose terms is almost square

Author(s): Shanta Laishram

Erdős conjectured that

$$n(n+d)\dots(n+(k-1)d) = y^2 \quad (1)$$

in positive integers n , $k \geq 3$, $d > 1$, y with $\gcd(n, d) = 1$, implies that k is bounded by an absolute constant. SHOREY and TIJDEMAN [16] showed that (1) implies that k is bounded by an effectively computable number depending only on $\omega(d)$, the number of distinct prime divisors of d . In this paper, an explicit bound for k in terms of $\omega(d)$ is presented.
