

Title: Sum of elements in finite Sidon sets. II

Author(s): Yuchen Ding

A set $S \subset \{1, 2, \dots, n\}$ is called a Sidon set if all the sums $a + b$ are different for different unordered pairs $(a, b) \in S^2$. Let S_n be the largest cardinality of a Sidon set in $\{1, 2, \dots, n\}$. In a former article, the author proved the following asymptotic formula

$$\sum_{a \in S, |S|=S_n} a = \frac{1}{2}n^{3/2} + O(n^{111/80+\varepsilon}),$$

where $\varepsilon > 0$ is an arbitrarily small constant. In this note, we improve the error term by showing that $O(n^{11/8} \log n)$ is true for almost all integers n in the above formula. Besides, we give some extensions of the former results. For any positive integers ℓ and s , we obtain the asymptotic formulae of the following summations

$$\sum_{\substack{S=\{a_1 < a_2 < \dots < a_t\} \\ S \subset [1, n] \text{ Sidon}}} a_i^\ell, \quad \text{and} \quad \sum_{\substack{S=\{a_1 < a_2 < \dots < a_t\} \\ S \subset [1, n] \text{ Sidon}}} i^s a_i^\ell,$$

when t is near the magnitude $n^{1/2}$.
