Title: Almost everywhere convergence of a subsequence of the logarithmic means of quadratical partial sums of double Walsh–Fourier series

Author(s): György Gát and Ushangi Goginava

The main aim of this paper is to prove that the maximal operator of the logarithmic means of quadratical partial sums of double Walsh–Fourier series is of weak type $(1, 1)$ provided that the supremum in the maximal operator is taken over special indices. The set of Walsh polynomials is dense in $L_1(I \times I)$, so by the well-known density argument we have that $t_{2^n} f(x^1, x^2) \rightarrow f(x^1, x^2)$ a.e. for all integrable two-variable functions f .
