

On the distribution mod 1 of $\alpha\sigma(n)$

By IMRE KÁTAI (Budapest)

Abstract. The sequence $x_n = F(n) + \alpha\sigma(n) \pmod{1}$ is investigated, where $\sigma(n)$ = sum of divisors of n , F is an additive arithmetical function. In an earlier paper De Koninck and the author proved that $x_n \pmod{1}$ is uniformly distributed if the approximation type of α is finite, and formulated the conjecture that it holds for every irrational α .

In this paper it is proved that the conjecture is not true in general, and it is true if $\alpha \in \mathcal{K}^*$. $\mathcal{K}^*$ is defined as follows. Let $M_x = \prod_p p^{r_p}$, p runs over the primes and r_p is the integer part of the number stated in the right hand side of (2.7). Let $\mathcal{K} = \mathcal{K}_x$ be the set of those irrational α , for which $\min_{H \mid M_x} \|H\alpha\|x > 1$ holds for every large x , $\mathcal{K}^* = \{\alpha \mid j\alpha \in \mathcal{K} \text{ for every } j = 1, 2, \dots\}$.

§ 1. Introduction

According to a reformulated version of a well known theorem of H. Daboussi (see DABOUSSI and DELANGE [1], [2]), for every additive arithmetical function $F(n)$ and any irrational α , the sequence $l_n := F(n) + \alpha n$ is uniformly distributed modulo 1. This famous theorem has a plenty of generalizations. It was proved in [3] that the same assertion holds for $l_n = F(n) + Q(n)$, where $Q(x) = \alpha_0 + \alpha_1 x + \dots + \alpha_k x^k \in \mathbb{R}[x]$, and at least one of $\alpha_1, \dots, \alpha_k$ is irrational.

Let $\|x\|$ stand for the distance between x and the closest integer. In [4] we proved the following result.

Theorem A. *Let α be a positive irrational number such that for each real*

Mathematics Subject Classification: 11K06.

Key words and phrases: arithmetical functions, distribution modulo 1, trigonometric sums, Daboussi's theorem.

number $\kappa > 1$ there exists a positive constant $c = c(\kappa, \alpha)$ for which the inequality

$$\|\alpha q\| > \frac{c}{q^\kappa} \quad (1.1)$$

holds for every positive integer q . Then $l_n = \alpha\sigma(n) + F(n)$ is uniformly distributed modulo 1 for every additive arithmetical function $F(n)$. Here $\sigma(n)$ is the sum of divisors of n .

We mentioned that similar assertion can be proved for the integer valued multiplicative function h instead of σ , where $h(p) = Q(p)$ for every prime p and $h(p^a) = \mathcal{O}(p^{ad})$ for some fixed number d for every prime p and every integer $a \geq 2$, where

$$Q(x) = a_k x^k + a_{k-1} x^{k-1} + \cdots + a_1 x + a_0 \in \mathbb{Z}[x],$$

$k \geq 1, a_k > 0$.

Especially, it is true for $h(n) = \varphi(n)$, where $\varphi(n)$ is Euler's totient function.

We formulated the conjecture that the assertion of Theorem A is true for every irrational α . We shall improve our theorem, and show that our conjecture is not true in general.

In [5] the function

$$\Delta(\alpha, x) = \frac{1}{\pi_2(x)} \max_{|X_p| \leq 1} \left| \sum_{\substack{p_1 p_2 \leq x \\ p_1 < p_2}} X_{p_1} X_{p_2} e(\alpha p_1 p_2) \right|$$

has been considered, where

$$\pi_2(x) = \sum_{\substack{p_1 p_2 \leq x \\ p_1 < p_2}} 1.$$

It was proved that $\Delta(\alpha, x) \rightarrow 0$ if α is not too well approximable by rationals, and the conjecture was formulated that this is true for every irrational α . HUIXUE LAO [6] proved that $\Delta(\alpha, x) \rightarrow 0$ if α was of finite type, in the sense that there exists a positive number σ such that $\|n\alpha\| > n^{-\sigma}$ for all sufficiently large n .

Finally Professor GLYN HARMAN [7] proved the conjecture. The main novelty of his method was that he could handle the case by the so called "major arc" estimate when α was very well approximable by rationals. Combining our method with his method we are able to prove the following theorems.

§ 2. Formulation of the results

2.1. Let $\mathcal{P}$ be the whole set of primes, p, q with or without indices denote prime numbers.

It is known that

$$\sum_{\substack{p \equiv -1 \pmod{k} \\ p < x}} \frac{1}{p} \leq c_1 \frac{\log \log x}{\varphi(k)} \quad (k \in \mathbb{N}) \quad (2.1)$$

if $x > 10$ (say), where c_1 is an absolute constant. (For a proof see [11]).

Let $c > 0$ be a constant, $x > 10$. Assume that S is such an integer depending on x for which

$$\#\{n \leq x \mid \sigma(n) \equiv 0 \pmod{S}\} > cx. \quad (2.2)$$

Let us write every n as Km , where K is the square full part and m is the square free part of n . It is clear that

$$\#\{n \leq x \mid K > Y\} \leq \sum_{K > Y} \frac{x}{K} \leq \frac{c_2 x}{\sqrt{Y}}. \quad (2.3)$$

Assume that $Y = \left(\frac{2c_2}{c}\right)^2$.

Then

$$\#\{n \leq x \mid n = Km, K < Y, \sigma(K)\sigma(m) \equiv 0 \pmod{S}\} > \frac{c}{2}x. \quad (2.4)$$

Let us write

$$S = \prod p^{\gamma_p}. \quad (2.5)$$

Assume that $p > c_3 \log \log x$. If $\gamma_p \geq 1$, then counting the integers $m \leq x$ in (2.4) satisfying $p \mid \sigma(m)$ is bounded by (see (2.1))

$$\sum_{\substack{q \equiv -1 \pmod{p} \\ q \leq x}} \frac{x}{q} < \frac{c_1 x \log \log x}{p-1}$$

and the right hand side should be larger than $\frac{c}{2}x$. Thus $p-1 < \frac{2c_1}{c} \log \log x$. We proved that $\gamma_p = 0$ if $p \geq \frac{2c_1}{c} \log \log x + 1$.

Let now $Y < p \leq \frac{2c_1}{c} \log \log x + 1$. We count those integers n for which $p^{\gamma_p} \mid \sigma(n)$, i.e. $p^{\gamma_p} \mid \sigma(m)$. This can be overestimated by the sum

$$\begin{aligned} x \sum_{r=1}^{\gamma_p} \sum_{\alpha_1 + \dots + \alpha_r = \gamma_p} \sum_{\substack{q_1 < \dots < q_r < x \\ p^{\alpha_j} \mid q_j - 1}} \frac{1}{q_1 \dots q_r} &\leq x \sum_{r=1}^{\gamma_p} \frac{1}{r!} \sum_{\alpha_1 + \dots + \alpha_r = \gamma_p} \frac{(c_1 \log \log x)^r}{\varphi(p^{\alpha_1}) \dots \varphi(p^{\alpha_r})} \\ &\leq \frac{2x}{\gamma_p!} \left(\frac{c_1 \log \log x}{p-1} \right)^{\gamma_p}. \end{aligned}$$

This number should be larger than cx , consequently

$$\frac{2}{\gamma_p!} \left(\frac{c_1 \log \log x}{p-1} \right)^{\gamma_p} > c,$$

i.e.

$$\gamma_p \leq \frac{c_1 e \log \log x}{p-1} \quad \text{if } x \text{ is large enough.} \quad (2.6)$$

Assume that $p < Y$. If $p^{\gamma_p} \mid \sigma(n)$, then $p^{\gamma_p - \Lambda} \mid \sigma(m)$, where $p^\Lambda \mid \sigma(K) \ll K \log \log K \ll Y \log \log Y$, whence we obtain that $\Lambda < c_4$. Furthermore as above we obtain that $\gamma_p - \Lambda \leq \frac{c_1 e \log \log x}{p-1}$ and so we have

$$\gamma_p \leq \begin{cases} \frac{c_1 e \log \log x}{p-1} & \text{if } Y < p \leq \frac{2c_1}{c} \log \log x + 1 \\ \frac{c_1 e \log \log x}{p-1} + c_4 & \text{if } p \leq Y \\ = 0 & \text{if } p > \frac{2c_1}{c} \log \log x + 1. \end{cases} \quad (2.7)$$

We proved

Lemma 1. Assume that $c > 0$ is a constant, and with some integer S

$$\frac{1}{x} \#\{n \leq x \mid \sigma(n) \equiv 0 \pmod{S}\} > c.$$

Let $S = \prod p^{\gamma_p}$. Assume that x is large enough, $x > y_0$. Then for the exponents γ_p (2.7) hold true. Consequently $S \ll \exp(c_1 e (\log \log x) [(\log \log \log x) + c_5])$ with suitable constants c_1, c_5 .

Remark. For some m let $\alpha_p(m)$ be that exponent for which $p^{\alpha_p(m)} \parallel \sigma(m)$. One can prove that

$$\alpha_p(m) > \frac{\log \log x}{(p-1)p} - \left(\frac{\log \log x}{p} \right)^{\frac{3}{4}} \quad (2.8)$$

holds for $2 \leq p \leq \sqrt{\log \log x}$ for all but $o(x)$ integers $m \leq x$. Let $l_p :=$ integer part of the right hand side of (2.8).

Let $T = T_x = \prod_{p \leq \sqrt{x_2}} p^{l_p}$. Then

$$\frac{1}{x} \#\{n \leq x \mid \sigma(n) \equiv 0 \pmod{T}\} = (1 + o_x(1)).$$

As a consequence we have

Lemma 2. *Let α be such an irrational number for which there is a sequence $x_1 < x_2 < \dots$ tending to infinity and there is a sequence of integers $\mathcal{D}_\nu$ dividing T_ν such that $\|\alpha\mathcal{D}_\nu\|x_\nu \rightarrow 0$ ($\nu \rightarrow \infty$). Then*

$$\frac{1}{x_\nu} \sum_{n \leq x_\nu} e(\alpha\sigma(n)) \rightarrow 1 \quad (\nu \rightarrow \infty)$$

and for all $\varepsilon > 0$:

$$\frac{1}{x_\nu} \#\{n \leq x_\nu \mid \|\alpha\sigma(n)\| > \varepsilon\} \rightarrow 0 \quad (\nu \rightarrow \infty). \quad (2.9)$$

Remark. Let $\alpha = \frac{1}{2^{t_1}} + \frac{1}{2^{t_2}} + \dots$, where $t_{k+1} = 2^{3^{t_k}}$. Assume that $t_1, \dots, t_k, x_1, \dots, x_{k-1}$ are chosen. Let $x_k = \exp(\exp(t_k + 1))$, $t_{k+1} > 3 \exp(t_k + 1)$. Then

$$\alpha\sigma(n) = \left(\frac{1}{2^{t_1}} + \dots + \frac{1}{2^{t_k}} \right) \sigma(n) + \left(\frac{1}{2^{t_{k+1}}} + \dots \right) \sigma(n) = u(n) + v(n),$$

and for $n \leq x_k$, $u(n)$ is integer for all but $o(x_k)$ integers, and from the known inequality $\sigma(n) \leq n \log \log n$ we obtain that

$$v(n) \leq \frac{2x_k \log \log x_k}{2^{t_{k+1}}} = \frac{2x_k(t_k + 1)}{2^{t_{k+1}}} = \eta_k,$$

$$\log \eta_k = \exp(t_k + 1) + \log(t_k + 1) - t_{k+1} \log 2 + \log 2,$$

and since $t_{k+1} \log 2 > 3(\log 2) \exp(t_k + 1)$, we have

$$\log \eta_k \leq \left(\log \frac{e}{8} \right) \exp(t_k + 1) + \log(t_k + 1) \rightarrow -\infty,$$

and so $\eta_k \rightarrow 0$.

We clearly have (2.9).

2.2. Let

$$M_x = \prod_p p^{r_p},$$

where r_p is defined by the integer parts of the numbers stated on the right hand side of (2.7).

Let $\mathcal{K}$ be the set of those irrational α , for which

$$\min_{H \mid M_x} \|H\alpha\|x > 1 \quad (2.10)$$

holds for every large x . Let $\mathcal{K}^*$ be the set of those α for which $j\alpha \in \mathcal{K}$ for every $j \in \mathbb{N}$.

Theorem 1. *Let $\alpha \in \mathcal{K}^*$. For some additive arithmetical function F let $l_n = F(n) + \alpha\sigma(n)$. Then the sequence l_n ($n \in \mathbb{N}$) is uniformly distributed mod 1, and the discrepancy can be overestimated by a sequence of real numbers ϱ_x , which does not depend on F , and $\varrho_x \rightarrow 0$.*

Another formulation of Theorem 1 is

Theorem A'. *Let $\alpha \in \mathcal{K}^*$, $\tilde{\mathcal{M}}$ = set of complex valued multiplicative functions satisfying $|f(n)| \leq 1$. Then*

$$\sup_{f \in \tilde{\mathcal{M}}} \frac{1}{x} \left| \sum_{n \leq x} f(n) e(\sigma(n)\alpha) \right| \rightarrow 0 \quad (\text{as } x \rightarrow \infty).$$

Remark. The above theorems remain valid if we change $\sigma(n)$ by $\varphi(n)$, where $\varphi(n)$ is Euler's totient function.

2.3. Let $Q \geq 3$ be an integer ($1 \leq l_1 < \dots < l_h < Q$) be coprime to Q , $h < \varphi(Q)$. Let $\mathcal{B}$ be the semigroup generated by the prime numbers p belonging to the arithmetical progressions $\equiv l_j \pmod{Q}$ ($j = 1, \dots, h$). Let $N_{\mathcal{B}}(x)$ be the number of elements of $\mathcal{B}$ less than or equal to x .

Theorem 2. *Let α be an irrational number. Then*

$$\lim_{x \rightarrow \infty} \frac{1}{N_{\mathcal{B}}(x)} \sup_{f \in \tilde{\mathcal{M}}} \left| \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} f(n) e(n\alpha) \right| = 0$$

§ 3. Proof of Theorem 1.

It is enough to prove that if $\alpha \in \mathcal{K}^*$, then

$$\frac{1}{x} \sum_{n \leq x} e(\alpha\sigma(n)) \rightarrow 0 \quad (x \rightarrow \infty). \quad (3.1)$$

The further part of the proof is the same as in [4].

Let $P(n)$ be the largest prime factor of n . Let $\varepsilon > 0$ be fixed. Writing each integer $n \leq x$ as $n = pm$, where $P(n) = p$, we have that if $\mathcal{N}_1 = \mathcal{N}_1(x) := \{n \leq x : P(n) \leq x^\varepsilon\}$, then

$$\lim_{\varepsilon \rightarrow 0} \lim_{x \rightarrow \infty} \frac{1}{x} \#\mathcal{N}_1 = 0.$$

On the other hand the contribution of those integers n for which $P(n)^2 \mid n$ is negligible.

Let

$$\mathcal{N}_2 = \mathcal{N}_2(x) := \{n \leq x : P(n) > x^\varepsilon, P(n)^2 \nmid n\}.$$

Let

$$\sum_{n \in \mathcal{N}_2} e(\alpha\sigma(n)) = \sum_{m \leq x^{1-\varepsilon}} \Sigma_m,$$

where

$$\begin{aligned} \Sigma_m &= e(\alpha\sigma(m)) \left(\sum_{p < \frac{x}{m}} e(\alpha\sigma(m)p) - \sum_{p < P(m)} e(\alpha\sigma(m)p) \right) \\ &= e(\alpha\sigma(m)) (\Sigma_m^{(1)} - \Sigma_m^{(2)}). \end{aligned}$$

In [4] we proved that $\sum \Sigma_m^{(2)} \ll \frac{1}{\varepsilon^2} \frac{x}{(\log x)^2} + \frac{1}{\varepsilon} \frac{x}{\log x} = o(x)$. Let $\tau = \frac{x}{(\log x)^{30}}$. In order to estimate $\Sigma_m^{(1)}$, we shall approximate $\alpha\sigma(m)$ by rational number $\frac{a_m}{q_m}$ satisfying

$$\left| \alpha\sigma(m) - \frac{a_m}{q_m} \right| < \frac{1}{q_m \tau}, \quad 1 \leq q_m < \tau.$$

In [4] we deduced from a theorem of I. M. Vinogradov that

$$\Sigma_m^{(1)} \ll \frac{\frac{x}{m}}{\log^2 \frac{x}{m}}, \quad \text{if } q_m > (\log x)^4 \quad (3.2)$$

(see Lemma 1 in [4]).

Assume now that $q_m \leq (\log x)^4$. Let $\gamma = \alpha\sigma(m)$. Then $|\gamma - \frac{a_m}{q_m}| < \frac{1}{q_m \tau}$, $\Sigma_m = \sum_{p \leq \frac{x}{m}} e(\gamma p)$.

By using Lemma 3.1 in VAUGHAN [8], after partial summation we obtain that

$$\Sigma_m^{(1)} \ll \frac{x}{q_m m (\log \frac{x}{m})}. \quad (3.3)$$

The sum of $|\Sigma_m^{(1)}|$ with $q_m > (\frac{1}{\varepsilon})^2$ is smaller than $\ll \varepsilon \frac{x}{\log x} \sum \frac{1}{m} \leq \varepsilon c x$ with an absolute constant c . To prove (3.1) it is enough to prove that for every fixed $l \leq (\frac{1}{\varepsilon})^2$, the number of those $m \leq x^{1-\varepsilon}$ for which $q_m = l$ is $o(x^{1-\varepsilon})$, as $x \rightarrow \infty$.

It is enough to prove that for every $U \in [x^\varepsilon, x^{1-\varepsilon}]$ and for every $l \leq (\frac{1}{\varepsilon})^2$ the number of $m \in [U, 2U]$ satisfying $q_m = l$ is $o_x(1)U$.

Let $(U \leq) m_1, \dots, m_R (< 2U)$ be those numbers for which $\|l\alpha\sigma(m_j)\| < \frac{1}{\tau}$. Let $\beta = l\alpha$. Since $\alpha \in \mathcal{K}^*$, therefore $\beta \in \mathcal{K}^*$, and so $\beta \in \mathcal{K}$. Let R_{m_j} be the integer closest to $\beta\sigma(m_j)$. Then $|\beta - \frac{R_{m_j}}{\sigma(m_j)}| < \frac{1}{\sigma(m_j)\tau}$. If $\frac{R_{m_i}}{\sigma(m_i)} \neq \frac{R_{m_j}}{\sigma(m_j)}$, ($i \neq j$) then

$$\frac{1}{\sigma(m_1)\sigma(m_2)} \leq \left| \frac{R_{m_1}}{\sigma(m_1)} - \frac{R_{m_2}}{\sigma(m_2)} \right| < \frac{1}{\tau} \left(\frac{1}{\sigma(m_1)} + \frac{1}{\sigma(m_2)} \right)$$

which is impossible. Thus $\frac{R_{m_j}}{\sigma(m_j)} = \frac{R}{S}$ ($j = 1, \dots, T$), $(R, S) = 1$. Thus $R\sigma(m_j) \equiv 0 \pmod{S}$, and so $\sigma(m_j) \equiv 0 \pmod{S}$ ($j = 1, \dots, T$). Let us assume that $T > cU$ with a positive constant. Then S should be very special: $S \mid M_U$. But this is impossible since $\beta \in \mathcal{K}$. The proof is completed.

§ 4. Proof of Theorem 2

The proof depends on the following

Lemma 3. *Let α be an irrational number.*

Then

$$\frac{1}{N_{\mathcal{B}}(x)} \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} e(\alpha n) \rightarrow 0 \quad (x \rightarrow \infty), \quad (4.1)$$

consequently the sequence $n\alpha$ ($n \in \mathcal{B}$) is uniformly distributed mod 1.

First we deduce Theorem 2 from Lemma 3.

Let

$$S(x) = \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} f(n)e(n\alpha). \quad (4.2)$$

Let K be a positive number, $p_1 < \dots < p_T$ be such primes $p_j \in \mathcal{B}$ for which

$$A_K := \sum_{j=1}^T \frac{1}{p_j} > K,$$

and $p_1 > K^2$.

Let $\mathcal{P}_K = \{p_1, \dots, p_T\}$,

$$\omega_{\mathcal{P}_K}(n) = \sum_{\substack{p|n \\ p \in \mathcal{P}_K}} 1. \quad (4.3)$$

One can prove the analogue of the Turán–Kubilius inequality, namely that

$$\frac{1}{N_{\mathcal{B}}(x)} \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} (\omega_{\mathcal{P}_K}(n) - A_K)^2 \leq CA_K, \quad (4.4)$$

whence we obtain that

$$\frac{1}{N_{\mathcal{B}}(x)} \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} |\omega_{\mathcal{P}_K}(n) - A_K| \leq \sqrt{CA_K}. \quad (4.5)$$

Let

$$S_1(x) = \sum_{\substack{n \leq x \\ n \in \mathcal{B}}} f(n) e(n\alpha) \omega_{\mathcal{P}_K}(n). \quad (4.6)$$

We have

$$|A_K S(x)| \leq |S_1(x)| + \sqrt{C A_K} N_{\mathcal{B}}(x). \quad (4.7)$$

We have

$$S_1(x) = \sum_{\substack{pm \leq x \\ pm \in \mathcal{B} \\ p \in \mathcal{P}_K}} f(pm) e(pm\alpha). \quad (4.8)$$

Let

$$S_2(x) = \sum_{\substack{pm \leq x \\ pm \in \mathcal{B} \\ p \in \mathcal{P}_K}} f(p) f(m) e(pm\alpha). \quad (4.9)$$

We have

$$|S_1(x) - S_2(x)| \leq 2 \sum_{\substack{p^2 \nu \leq x \\ p^2 \nu \in \mathcal{B}}} 1 \leq c N_{\mathcal{B}}(x) \sum_{j=1}^T \frac{1}{p_j^2} \leq \frac{c}{K} N_{\mathcal{B}}(x). \quad (4.10)$$

Furthermore

$$S_2(x) = \sum_{m \leq \frac{x}{p_1}} f(m) \Sigma_m, \quad \Sigma_m = \sum_{p_j \leq \frac{x}{m}} f(p_j) e(\alpha p_j m). \quad (4.11)$$

Thus

$$|S_2(x)|^2 \leq \sum_{\substack{m \leq \frac{x}{p_1} \\ m \in \mathcal{B}}} |f(m)|^2 \sum_{\substack{m \leq \frac{x}{p_1} \\ m \in \mathcal{B}}} |\Sigma_m|^2 = S \cdot H. \quad (4.12)$$

It is clear that $S \ll N_{\mathcal{B}}(\frac{x}{p_1}) \ll \frac{1}{p_1} N_{\mathcal{B}}(x)$.

$$H = \sum_{m \in \mathcal{B}} \sum_{\substack{p_i, p_j \leq \frac{x}{m} \\ p_i, p_j \in \mathcal{B}}} f(p_i) \overline{f(p_j)} e((p_i - p_j)\alpha m) = H_1 + H_2.$$

In H_1 we sum over those m, p_i, p_j for which $i = j$, consequently

$$H_1 \ll \sum_{j=1}^T N_{\mathcal{B}}\left(\frac{x}{p_j}\right) \leq c N_{\mathcal{B}}(x) \sum_{j=1}^T \frac{1}{p_j},$$

i.e.

$$H_1 \leq c_3 A_K N_{\mathcal{B}}(x),$$

where c_3 is an absolute constant.

In H_2 we sum over those (m, p_i, p_j) for which $i \neq j$. Changing the order of summation, for fixed i, j

$$\sum_{\substack{m \leq \min\left(\frac{x}{p_i}, \frac{x}{p_j}\right) \\ m \in N_{\mathcal{B}}(x)}} e(\alpha(p_i - p_j)m)$$

is $o(N_{\mathcal{B}}(x))$ due to Lemma 3, since $\alpha(p_i - p_j)$ is an irrational number also.

Hence we obtain that, for every large x , with a constant C ,

$$\left| \frac{A_K S(x)}{N_{\mathcal{B}}(x)} \right| \leq \sqrt{C A_K} + 2 \frac{A_K}{K^2} + \frac{2}{K} \sqrt{A_K}, \quad (4.13)$$

consequently

$$\limsup_{x \rightarrow \infty} \frac{|S(x)|}{N_{\mathcal{B}}(x)} \leq \frac{\sqrt{C}}{\sqrt{A_K}} + \frac{2}{K^2} + \frac{2}{K \sqrt{A_K}}. \quad (4.14)$$

Since K is arbitrarily large, $A_K > K$, we obtain that the left hand side of (4.14) is 0.

Finally we prove Lemma 3.

Let $\varepsilon > 0$ be fixed. Let us write each $n \in \mathcal{B}$ as $n = pm$, where $P(n) = p$ is the largest prime factor of n . Let $\mathcal{N}_1 = \mathcal{N}_1(x) := \{n \leq x, n \in \mathcal{B}, P(n) \leq x^\varepsilon\}$. One can prove easily that

$$\#\mathcal{N}_1(x) \ll \varepsilon N_{\mathcal{B}}(x).$$

According to a well known theorem due to WIRSING [10]

$$N_{\mathcal{B}}(x) = c \frac{x}{(\log x)^E} (1 + o_x(1))$$

$$E = 1 - \frac{h}{\varphi(Q)},$$

we obtain that $N_{\mathcal{B}}\left(\frac{x}{u}\right) \leq \frac{c}{u} N_{\mathcal{B}}(x)$ if $1 \leq u \leq x^\lambda$, where $(0 \leq) \lambda < 1$, $c = c(\lambda)$. Let $\mathcal{N}_2 = \mathcal{B} \setminus \mathcal{N}_1$. Then

$$\sum_{\substack{n \in \mathcal{N}_2 \\ n \leq x}} e(\alpha n) = \sum_{\substack{m \leq x^{1-\varepsilon} \\ m \in \mathcal{B}}} \sum_{\substack{P(m) < p < \frac{x}{m} \\ p \in \mathcal{B}}} e(\alpha pm) = \sum_m \Sigma_m.$$

Further write

$$\Sigma_m = \sum_{\substack{p < \frac{x}{m} \\ p \in \mathcal{B}}} e(\alpha mp) - \sum_{\substack{p < P(m) \\ p \in \mathcal{B}}} e(\alpha mp) = \Sigma_m^{(1)} - \Sigma_m^{(2)}.$$

Assume that $1 \leq m \leq x^{1-\varepsilon}$. Let $\tau_m = \frac{x}{m}(\log x)^{-40}$,

$$\left| \alpha m - \frac{a_m}{q_m} \right| \leq \frac{1}{q_m \tau_m}, \quad 1 \leq q_m \leq \tau_m, \quad (a_m, q_m) = 1. \quad (4.15)$$

According to a result of A. BALOG and A. PERELLI [9], if $|\alpha - \frac{a}{q}| \leq \frac{2}{N}$, $(a, q) = 1$, $h = (q, d)$, then

$$\sum_{\substack{n \leq N \\ n \equiv f \pmod{d}}} \Lambda(n) e(n\alpha) \ll \left(\frac{hN}{d\sqrt{q}} + \frac{\sqrt{qN}}{\sqrt{h}} + \left(\frac{N}{d} \right)^{\frac{4}{5}} \right) (\log N)^3. \quad (4.16)$$

By using partial integration, the inequality remains true, if the left hand side is changed to

$$\sum_{\substack{p \leq N \\ p \equiv f \pmod{d}}} e(p\alpha). \quad (4.17)$$

Let us apply the inequality (4.16), (4.17) for αm instead of α , and for $d = Q$, $f = l_j$, in the case if $\tau_m \geq (\log x)^{40}$.

Since l_j, Q, d are bounded as $x \rightarrow \infty$, we obtain that

$$\Sigma_m^{(1)} \ll \left\{ \frac{x}{m\sqrt{q_m}} + \left(\frac{x}{m} q_m \right)^{\frac{1}{2}} + \left(\frac{x}{m} \right)^{\frac{4}{5}} \right\} (\log x)^3 \ll \frac{x}{m(\log x)^{17}} + \frac{x^{\frac{4}{5}}}{m^{\frac{4}{5}}},$$

and so

$$\sum_{q_m > (\log x)^{40}} |\Sigma_m^{(1)}| \ll \frac{x}{(\log x)^{16}}.$$

It is clear that

$$\frac{1}{\varphi(Q)} \sum_{a=0}^{Q-1} e\left(\frac{(p-l)a}{Q}\right) = \begin{cases} 1, & \text{if } p \equiv l \pmod{Q}, \\ 0, & \text{otherwise.} \end{cases}$$

We have

$$\Sigma_m^{(1)} = \sum_{j=1}^h \frac{1}{\varphi(Q)} \sum_{a=0}^{Q-1} e\left(\frac{-al_j}{Q}\right) \sum_{p < \frac{x}{m}} e\left(\left(\alpha m + \frac{a}{Q}\right)p\right)$$

whence

$$|\Sigma_m^{(1)}| \leq \sum_{a=0}^{Q-1} \left| \sum_{p < \frac{x}{m}} e \left(\left(\alpha m + \frac{a}{Q} \right) p \right) \right| = \sum_{a=0}^{Q-1} |\Sigma_{m,a}^{(1)}|.$$

If (4.15) holds, then

$$\left| \alpha m + \frac{a}{Q} - \frac{E_m}{L_m} \right| < \frac{1}{q_m \tau_m},$$

where $\frac{E_m}{L_m} = \frac{a_m}{q_m} + \frac{a}{Q}$, $(E_m, L_m) = 1$. It is clear that $\frac{q_m}{Q} \leq L_m \leq q_m Q$ if $q_m > Q$.

Let us assume that $q_m \leq (\log x)^{40}$. By using Lemma 3.1 in VAUGHAN [8], after partial summation, we obtain that

$$\Sigma_{m,a}^{(1)} \ll \frac{x}{L_m m \log \frac{x}{m}}.$$

Hence we obtain that

$$\sum_{L_m > R} \Sigma_{m,a}^{(1)} \ll \frac{x}{R} \sum_{m \leq x^{1-\varepsilon}} \frac{1}{m \log \frac{x}{m}} \ll \frac{N_{\mathcal{B}}(x)}{R}.$$

Let a be any of $a = 0, 1, \dots, Q-1$.

Let l be a fixed integer, and consider those m for which $q_m = l$. Let $x^\varepsilon \leq U \leq x^{1-\varepsilon}$, and consider the set of integers $m \in \mathcal{B}$ in $[U, 2U]$ for which

$$\left| m\alpha - \frac{a_m}{l} \right| < \frac{1}{l\tau_m}.$$

Assume that these numbers are $m_1, \dots, m_T$. Then $|l\alpha - \frac{a_m}{m}| < \frac{1}{m_\tau}$. If $|l\alpha - \frac{a_{m_u}}{m_u}| < \frac{1}{m_u \tau_m}$ holds for $u = i, j$, then

$$\left| \frac{a_{m_j}}{m_j} - \frac{a_{m_i}}{m_i} \right| < \frac{2}{\tau_{m_i}} \left(\frac{1}{m_i} + \frac{1}{m_j} \right)$$

which implies that $\frac{a_{m_u}}{m_u} = \frac{R}{S}$ ($u = 1, \dots, T$), $(R, S) = 1$. Thus $R_{m_u} \equiv 0 \pmod{S}$ ($u = 1, \dots, T$). S cannot be bounded as $x \rightarrow \infty$. Hence we obtain that

$$T \leq \#\{m \in [U, 2U], m \in \mathcal{B}, m \equiv 0 \pmod{S}\} \leq \frac{N_{\mathcal{B}}(2U)}{S}.$$

Since α is irrational, therefore $S \rightarrow \infty$ as $x \rightarrow \infty$ uniformly as U varies in $[x^\varepsilon, x^{1-\varepsilon}]$. Thus we proved that

$$\sum_{\substack{m \leq x^{1-\varepsilon} \\ m \in \mathcal{B}}} |\Sigma_m^{(1)}| = o_x(1) N_{\mathcal{B}}(x).$$

In order to estimate $\Sigma_m^{(2)}$, observe that $|\Sigma_m^{(2)}| \leq c \frac{P(m)}{\log 2P(m)}$, and so

$$\sum_m |\Sigma_m^{(2)}| \leq c \sum_{\substack{p \leq x^{1-\varepsilon} \\ p \in \mathcal{B}}} \frac{p}{\log p} \sum_{\substack{pr \leq x^{1-\varepsilon} \\ P(r) \leq p \\ p^2 r \leq x \\ r \in \mathcal{B}}} 1 = \Sigma_A + \Sigma_B.$$

In Σ_A we sum over $p \leq x^\varepsilon$, and in Σ_B over $p > x^\varepsilon$. Then

$$\begin{aligned} \Sigma_A &\ll \sum_{\substack{p \leq x^\varepsilon \\ p \in \mathcal{B}}} \frac{p}{\log p} \cdot N_{\mathcal{B}}\left(\frac{x^{1-\varepsilon}}{p}\right) \ll N_{\mathcal{B}}(x^{1-\varepsilon}) \sum_{p \leq x^\varepsilon} \frac{1}{\log p} \\ &\ll \frac{x^\varepsilon}{\varepsilon \log x} N_{\mathcal{B}}(x^{1-\varepsilon}) \ll \frac{N_{\mathcal{B}}(x)}{\varepsilon \log x} = o_x(1) N_{\mathcal{B}}(x), \end{aligned}$$

Furthermore,

$$\Sigma_B \ll \sum_{x^\varepsilon < p \leq x} \frac{p}{\log p} \sum_{\substack{r \leq \frac{x}{p^2} \\ P(r) \leq p \\ r \in \mathcal{B}}} 1 \ll \sum_{x^\varepsilon < p \leq x} \frac{p}{\log p} \cdot \frac{x}{p^2} \ll \frac{1}{\varepsilon} \frac{x}{\log x} = o_x(1) N_{\mathcal{B}}(x).$$

The proof is completed.
